Linux

Installation guide

2.1.1 Hardware Requirements

Windows

Hardware Items	Required
CPU	Intel 486 Processor
Memory	128M RAM
Disk Space	- Minimal (HTTP only): 650MB - Standard Edition : 1.6GB - Enterprise Edition : 2.56GB
Temp Disk Space	500MB

Solaris

Hardware Items	Required
CPU	Sparc Processor
Memory	128MB RAM
Disk Space	- Minimal (HTTP Only) : 650MB - Standard Edition : 1.6GB - Eenterprise Edition : 3.30 GB

2.1.2 Software Requirement

Windows

Software Items	Version
Operating System	- Microsoft Windows NT ServicePack 3 (minimum) or 5 (recommended) - Microsoft Windows 2000
Virtual Memory	360MB

Solaris

Software Items	Version
Operating System	Solaris 2.6 Motif Runtime patch: 105284-20 or higher Kernel Jumbo patch: 105181-20 or higher Linker patch: 107733-06 or higher Libthread patch: 105568-16 or higher Libc patch: 105210-27 or higher

Software Items	Version
	XIM patch: 106040-13 or higher
	Solaris 2.7 Libthread patch: 106980-10 or higher Kernal cluster patch106541-09 or higher /kernal/fs/sockfs patch: 109104-01 or higher /usr/lib/fs/fsck patch: 107544-02 or higher Motif Runtime patch: 107081-19 or higher XIM patch: 107636-03 or higher OpenWindows patch: 108376-03 or higher
	Solaris 2.8 None required at this time

3.3 Configuration Tools

Configuration Tool .

3.3.1 HTTP Server Only (Minimal Install)

1. Net8 Configuration Assistant
2. Starting web server in non-SSL mode on port 7777 (in Solaris) / Starting Oracle HTTP service (on port 80 in Windows NT)
3. Oracle Portal 3.0 Configuration Assistants

3.3.2 Standard Edition (SE)

1. Net8 Configuration Assistant
2. Oracle Database Configuration Assistant
3. Starting web server in non_SSL mode on port 7777 (in Solaris) / Starting Oracle HTTP service (on port 80 in Windows NT)
4. Oracle Portal 3.0 Configuration Assistants

3.3.3 Enterprise Edition (EE)

1. Oracle Database Cache Configuration Assistant
2. Oracle Web Cache Configuration Assistant
3. Oracle Portal 3.0 Configuration Assistant
4. Starting web server in non_SSL mode on port 7777 (in Solaris) / Starting Oracle HTTP service (on port 80 in Windows NT)
5. Starting Forms Server (Not a tool in NT. ORCA installer will start the service)
- 6) Starting Reports Server(Not a tool in NT,ORCA installer will start the service)
7. Starting Discoverer 4iViewer Server(Not a tool in NT. ORCA installer will start the service. This is not a selectable item in Windows NT)
8. Oracle Management Server

3.3.4 Installation 가 Configuration Tools

iFS Configuration Assistant

Command : <ORACLE_HOME>/ifs1.1/bin/ifsconfig.bat on Windows

<ORACLE_HOME>/ifs1.1/bin/ifsconfig.sh on Solaris

Note: The ftp server's default port# is 21. It should be changed so that it does not conflict with the default port#.

3.3.5 OUI 가 Configuration Tools

1. Net8 Configuration Assistant : Will add later
 2. Oracle Database Configuration Assistant : <ORACLE_HOME>/bin/dbassist (For Solaris)
<ORACLE_HOME>/bin\DBAssist.bat (For Windows)
 3. Oracle Portal 3.0 Configuration Assistant : <ORACLE_HOME>/assistance/opca/launch.sh
(launch.sh on Solaris and launch.bat on Windows)
 4. Oracle Database Cache Configuration Assistant : <ORACLE_HOME>/bin/wtacca -create -typical
- Note: To deconfigure Database Cache : <ORACLE_HOME>/bin/wtacca -deinstall
5. Oracle Management Server : <ORACLE_HOME>/bin/emca
 6. iFS Configuration Assistant : <ORACLE_HOME>/ifs1.1/bin/ifsconfig.sh (ifsconfig.sh on Solaris and ifsconfig.bat on Windows)

4. Client CD

Client CD is for Windows Platforms only.

The win32 client CD for 9i Application Server contains the following products:

Oracle Portal-to-Go Client 1.0.2.2.0a

Oracle OEM for iCache Client 1.0.2.0.0.1115

4.1. Oracle Portal-to-Go Client Requirements

Oracle Portal-to-Go client

Hardware Items	Required
Operating System	Windows NT 4.0 (with Service Pack 4.0) or higher
CPU	Pentium 266
Memory	At least 64 MB RAM for running both the Oracle Portal-to-Go Service Designer and Portal-to-Go Web Integration Developer; at least 32 MB RAM for running the Portal-to-Go Service Designer.
Disk Space	40 MB for running both the Oracle Portal-to-Go Service Designer and Portal-to-Go Web Integration Developer; at least 20 MB for running the Portal-to-Go Service.
JDK 1.2.2	The client system requires JDK 1.2.2. You can install JDK 1.2.2 for Windows NT from the client CD-ROM. You should ensure that the JDK directory is the first entry in the system environment path

5. Post Installation

6.1.8.5 Migrating OAS PL/SQL Cartridge using flexible parameter passing to MOD_PLSQL

: <Note:124474.1>

Title: Migrating OAS PL/SQL Cartridge using flexible parameter passing to MOD_PLSQL

Flexible parameter passing can be used in OAS PL/SQL cartridge i.e. HTML forms can be used from which any number of elements can be selected. Overloaded procedures can be used to handle each possible combination but OAS makes it possible to define/invoke a procedure regardless of which elements were chosen. In the query string all the name-value pairs are passed to the procedure, and it has the following signature:

```

proc_name(
    num_entries IN NUMBER,
    name_array  IN OWA.vc_arr,
    value_array IN OWA.vc_arr,
    reserved   IN OWA.vc_arr)

```

where:

proc_name is the name of the PL/SQL procedure that you are invoking.
num_entries specifies the number of name-value pairs in the query string.
name_array specifies the names from the query string.
value_array specifies the values from the query string.
reserved is not used.

Example

```

CREATE OR REPLACE PROCEDURE first
IS
BEGIN
    http.formOpen('second');
    http.formText('p_param1');
    http.para;

    http.formSelectOpen('p_param2', cattributes=>'multiple');
    http.formSelectOption('one');
    http.formSelectOption('two');
    http.formSelectOption('three');
    http.formSelectClose;
    http.para;
    http.formHidden('p_param3', 'hidden');
    http.formSubmit(cvalue=>'Submit');
    http.formClose;
END;
/

CREATE OR REPLACE PROCEDURE second
(NUM_ENTRIES IN NUMBER
,NAME_ARRAY IN owa.vc_arr
,VALUE_ARRAY IN owa.vc_arr
,RESERVED IN owa.vc_arr
)
IS
BEGIN
    http.p('Number of parameters: ' || TO_CHAR(num_entries));
    http.br;
    http.p('Name and value of the parameters:');
    FOR i IN 1..name_array.count LOOP
        http.p('Name: ' || name_array(i));
        http.br;
        http.p('Value: ' || value_array(i));
        http.br;
    END LOOP;
    http.br;

```

```
END;  
/
```

If we run the above example using mod_plsql we get the following message:

```
second: SIGNATURE (parameter names) MISMATCH  
  
VARIABLES IN FORM NOT IN PROCEDURE: P_PARAM1,P_PARAM2,P_PARAM3  
  
NON-DEFAULT VARIABLES IN PROCEDURE NOT IN FORM:  
NUM_ENTRIES,NAME_ARRAY,VALUE_ARRAY,RESERVED
```

```
DAD name: www_proba  
PROCEDURE   : second  
URL         : http://hostname:port/pls/DAD/second  
PARAMETERS :  
=====
```

P_PARAM1:	joke
P_PARAM2:	two
P_PARAM3:	Hidden

Solution Description

In order to use flexible parameter passing with mod_plsql the procedure name has to be prefixed with a '!'. So the form generating procedure has to be modified in the following way:

```
CREATE OR REPLACE PROCEDURE first  
IS  
BEGIN  
  http.formOpen('!second');  
  http.formText('p_param1');  
  http.para;  
  
  http.formSelectOpen('p_param2', cattributes=>'multiple');  
  http.formSelectOption('one');  
  http.formSelectOption('two');  
  http.formSelectOption('three');  
  http.formSelectClose;  
  http.para;  
  http.formHidden('p_param3', 'hidden');  
  http.formSubmit(cvalue=>'Submit');  
  http.formClose;  
END;  
/
```

6.1.8.8

Using the PL/SQL Gateway authentication schemes

There are three types of authentications:

* Static Authentication where username/password are hard coded as part of the DAD in the configuration file and thus when you use that DAD, you are always forced to work out of the username schema defined in the config file.

* Dynamic Authentication where the username/password information isn't present as part of the DAD in the configuration file, and thus the user is prompted for this information.

* Single-Sign-On

There is a provision to restrict access to your PL/SQL Gateway configuration area, e.g.
[http://\[hostname\]:\[port\]/pls/admin_/gateway.htm](http://[hostname]:[port]/pls/admin_/gateway.htm)

This is done by changing the parameter "administrators" in your [WVGATEWAY] section of `wdbsvr.app`. This parameter is set to "all" by default, and can be set to a list of comma separated values indicating the list of users which will have access to the `gateway.htm` page.

For e.g. setting "administrators=scott,system" allows only users "scott" and "system" to access `gateway.htm`.

In order to get prompted for a password you need to access the "admin_" pages thru a DAD with "dynamic authentication" enabled (no user/password specified). You also may want to make this DAD your default DAD by setting the parameter "defaultDAD" in the [WVGATEWAY] section of `wdbsvr.app`. This allows calling

[http://\[hostname\]:\[port\]/pls/admin_/gateway.htm](http://[hostname]:[port]/pls/admin_/gateway.htm)

(would otherwise give you "document contained no data") instead of

[http://\[hostname\]:\[port\]/pls/\[DADnouser&passwd\]/admin_/gateway.htm](http://[hostname]:[port]/pls/[DADnouser&passwd]/admin_/gateway.htm)

Notes:

Do not specify users as administrators for which a DAD with static authentication exists (even if its not your default DAD). Otherwise by accessing a URL like

[http://\[hostname\]:\[port\]/pls/\[DADwithscott&passwd\]/admin_/gateway.htm](http://[hostname]:[port]/pls/[DADwithscott&passwd]/admin_/gateway.htm)

would get you access as scott (if scott is specified as administrator)

Be aware that the "administrators=username" can actually take values like "administrators=username@tns_alias". This way only user "username" which connects to database with alias "tns_alias" can access the admin page.

So if you designate user "scott" in database "db1" as the administrator, this will ensure that user "scott" of database "db2" cannot access the admin page.

Pros:

PLSQL gateway's way of dealing with authentication is to use a cookie (WDB_GATEWAY_LOGOUT) in conjunction with the Basic Authentication info. This allows you to de-authenticate(!) by running the built-in command "logmeoff".

i.e. `http://[hostname]:[port]/pls/[DADusedforauth]/logmeoff`.

You have to specify the DAD!!! (`http://[hostname]:[port]/pls/logmeoff` would give an error!)

Cons:

The specified administrators can not be the same users used in a static DAD unless you want to open a backdoor (see note above). If you set the DAD used for auth to be the default DAD, your application URL eventually needs to contain the DAD name (if using a different DAD)

You can use the Apache "rewrite" methods to alias a URL (see <Note:108660.1>)

How to Configure Apache Jserv For Multiple JVMs for Load Balancing

Note:120741.1

Multiple JVM Load Balancing Apache Jserv Configuration
가

1. MULTIPLE JVMs ON SAME SERVER

Apache allows you work with a few JVMs. Each JVM can require considerable memory and processor resources. If you execute more copies of Apache Jserv on a same virtual host, each JVM needs a dedicate port. The configuration files can be identical except for the port numbers.

The following example shows how to configure Apache JServ with multiple JVMs for each servlet zone:

```
<IfModule mod_jserv.c>
  ApJServManual on
  ApJServDefaultProtocol ajpv12
  ApJServMount /servlets1 ajpv12://localhost:9001/jvm1
  ApJServMount /servlets1 ajpv12://localhost:9001/jvm2
  ApJServLogFile /db/jserv/apache/logs/mod_jserv.log

<Location /status/jserv/>
  SetHandler jserv-status
  order deny,allow
  allow from all
</Location>

</IfModule>
```

The request containing /servlets1 are managed by the zone jvm1, which listens on port 9001.

The request containing /servlets2 are managed by the zone jvm2, which listens to port 9002.

Two instances of the JVM must be launched, one which listens on port 9001 and the other on port 9002

For example, two properties files:

```
java org.apache.jserv.JServ /usr/local/apache/conf/jvm1.properties
```

```
java org.apache.jserv.JServ /usr/local/apache/conf/jvm2.properties
```

2. MULTIPLE JVMs ACROSS DIFFERENT SERVERS

For use multiple JVMs on e different servers, Apache Jserv must be in Manual Mode. Using multiple servers allows management transfer from the main JVM towards other computers. You can thus combine the use of NT, Solaris, Linux, and/or HP by configuring the iAS Jserv.conf file like this:

```
<IfModule mod_jserv.c>
    ApJServManual on
    ApJServDefaultProtocol ajpv12
    ApJServMount /servlets1 ajpv12://server1/zone1
    ApJServMount /servlets2 ajpv12://server2/zone2
    ApJServLogFile /db/jserv/apache/logs/mod_jserv.log

<Location /status/jserv/>
    SetHandler jserv-status
    order deny,allow
    allow from all
</Location>

</IfModule>
```

With the above configuration, the requests starting with /servlets1 are to be managed by the instance of Apache Jserv on the server1. The requests starting with /servlets2 managed by the instance of Apache Jserv on the server2.

Of course, you must install Apache Jserv on the 2 servers and configure the zone and properties files for the Jserv engine. In certain cases, it is also necessary to indicate address IP of the server Web in the input security.allowAddresses of the properties file of the engine of each servlet.

Another example of Jserv.conf file using the load balanced JVMs:

```
<IfModule mod_jserv.c>
ApJServManual on
ApJServDefaultProtocol ajpv12

ApJServShmFile logs/jserv_shm
ApJServBalance set1 JVM1
ApJServBalance set1 JVM2
ApJServBalance set1 JVM3
ApJServBalance set1 JVM4

ApJServHost JVM1 ajpv12://127.0.0.1:8017
ApJServHost JVM2 ajpv12://127.0.0.1:8016
ApJServHost JVM3 ajpv12://127.0.0.1:8015
ApJServHost JVM4 ajpv12://127.0.0.1:8014
ApJServRoute JS1 JVM1
ApJServRoute JS2 JVM2
ApJServRoute JS3 JVM3
ApJServRoute JS4 JVM4

ApJServMount /root balance://set1/root
ApJServMount /servlets balance://set1/root
ApJServMount /servlet balance://set1/root

<Location /status/jserv/>
  SetHandler jserv-status
  order deny,allow
  allow from all
</Location>

</IfModule>
```

6.1.15 9iAS HTTP Listener 가

Note:135231.1

Oracle 9iAS가
configuration

Unix

가 Listener
Listener 가
가

, mod_plsql, mod_jserv
가 가 ,

script .

1. Apache module

Port

Apache configuration file

Httpds.conf file (iAS 8I) httpd.conf (9iAS) configuration directory
(<ORACLE_HOME>/Apache/Apache/conf)

httpds_<list>.conf

where:

<list> represents a short arbitrary name for the listener

e.g. httpds_www2.conf

The example 'apctl' script (provided as Appendix A) accepts an additional listener name parameter which is used to determine which of the multiple listener configuration files should be used.

The following illustrates lines changed after duplicating the

httpds.conf file to become httpds_www2.conf:

```
LockFile /iAS/Apache/Apache/logs/httpds_www2.lock
PidFile /iAS/Apache/Apache/logs/httpds_www2.pid
ScoreBoardFile /iAS/Apache/Apache/logs/httpds_www2.scoreboard
```

```

ErrorLog /iAS/Apache/Apache/logs/https_error_log_www2
CustomLog /iAS/Apache/Apache/logs/https_access_log_www2 common
ErrorLog /iAS/Apache/Apache/logs/https_error_log_www2
TransferLog /iAS/Apache/Apache/logs/https_access_log_www2
CustomLog /iAS/Apache/Apache/logs/https_ssl_request_log_www2 \
    "%t %h %{SSL_PROTOCOL}x %{SSL_CIPHER}x \"%r\" %b"
ErrorLog /iAS/Apache/Apache/logs/https_error_log_www2
TransferLog /iAS/Apache/Apache/logs/https_access_log_www2

```

NOTE: The above lines are scattered at various locations in the conf file and the duplicate parameters are located in various Virtual Host or SSL specific configuration sections.

For consistency, apply the additional prefix at every location (even in those sections not currently being used). It is likely to be necessary to un-comment some lines so that default values do not result in all listeners sharing the same file.

JSERV NOTE: Since each listener configuration in this approach utilizes the same module configuration files, it may be sensible to configure MOD_JSERV not to attempt to start Servlet Engines automatically. Doing so will avoid error messages from the second and subsequent listeners reporting that they cannot start an additional instance of the Servlet engine since the port is already in use.

If you elect to manually start the servlet engine then set the ApJServManual parameter in the jserv.conf file to ON. To aid manual startup of the Servlet Engine please see the example script provided by Note:123533.1, "Example script to manually start the JVM for the MOD_JSERV servlet engine"

If you are happy to remember that some errors about failure to start the Servlet JVM these should be expected when multiple listeners share the same JSERV.CONF file, then it should not be harmful to leave the ApJServManual parameter at its default OFF value.

Apctl

For example:

```
% apctl start www2
```

starts the listener whose configuration is specified in the file

https_www2.conf, whereas:

```
% apctl start
```

will still start the default listener i.e. the one specified by

the file https.conf.

To ensure complete separation of the listeners from one another, it is necessary to make modifications to the newly copied configuration file so that files tracking information unique to each listener (e.g. lock and PID files) do not overlap.

Searching through the file for 'httpds' will help highlight the parameters which should be changed. Again adding a `_<LIST>` suffix these parameters is a sensible approach to guaranteeing uniqueness.

TIP: To further differentiate between configuration files and log files the 'apctl' script (see Appendix A) allows an alternate naming convention for listener configuration files.

In the event an environment variable `APCTL_USE_SUBDIR` is set to the value 'TRUE' the listener config file will be expected to retain the name `httpds.conf`, but be located in a sub-directory of the same name as the listener, e.g. `Apache/conf/www2/httpds.conf`

In this case, the listener log files such as error and xlf logs will also be located beneath the default log location (relative to the configuration root) but will be in a sub-directory with the name associated with that listener.

For further details about the operation of the example 'apctl' script, please see the comments embedded within the script itself.

2. Apache module configuration Multiple Listener

This is probably the more complex of the two cases and is really the same as supporting two entirely different web sites from the same set of binaries. An example here would be to facilitate two small development teams working on the same web server host.

In this case not only are the listener configuration files different but they must reference different sets of configuration files for each of the modules (e.g. `MOD_PLSQL`, `MOD_JSERV` etc.)

In this case, the recommended approach is to duplicate the whole `ORACLE_HOME/Apache` directory to an additional location outside of the `ORACLE_HOME` directory:

```
% cp -r $ORACLE_HOME/Apache /web/config1
```

After having done this, detailed inspection of all configuration files will be needed to identify modifications necessary to use only configuration files from within the new directory tree.

Starting with the listener, configuration file (httpds.conf) locate any match in the file which points to the original configuration directory and modify it to point to the new configuration root directory.

It should be possible to achieve this using the search and replace capabilities of a suitable editor such as vi or emacs. However, caution should be taken to ensure that references to binary files (e.g. libraries referenced by LoadModule directives) remain pointing to their original location.

Next, recursively inspect all configuration files which the httpds.conf file references with an 'include' directive and any file which is also included by this file.

The following is a list of files (relative to the root of the newly copied directory tree) which should be examined in this way:

- Apache/conf/oracle_apache.conf
- Jserv/etc/jserv.conf
- Jserv/etc/jserv.properties
- Jserv/etc/zone.properties
- Ojsp/conf/ojsp.conf
- modplsql/cfg/plsql.conf

NOTE: The above list is not intended to be exhaustive so it is advisable to begin by traveling to each configuration directory and using a tool such as grep to list any occurrence of the path to the original configuration root. Then, for each match found, edit the file where that match was contained and review in the context of this file if the change should be made.

To support this approach, the 'apctl' script (see Appendix A) uses an optional environment variable 'APCTL_CONFIG_ROOT' which can be used to specify the path to the root of the configuration hierarchy which should be used.

For further details about the operation of the example 'apctl' script, please see the comments embedded within the script itself.

TIP: To help ensure that all settings have been correctly modified it can be useful to:

- temporarily rename the original configuration root so that any references to these configuration files will no longer be found;
- startup and test the newly duplicated configuration and test the base functionality of the various modules to ensure that they still work as expected;
- review all log files for evidence of any errors indicating that files cannot be found to ensure that the cause of these errors is not a reference which should have been updated to point to the new directory;

3. 'apctl' script

To ensure that documentation about the operation of this script is always available, notes about it's usage and operation have been embedded as comments within the script itself.

```
----- Code begins here -----

#!/bin/sh

#####
# Script: APCTL
# -----
# Extended APACHECTL script supporting startup of multiple
# listeners running on different ports as identified by
# files of the format 'httpds_<LISTENER NAME>.conf'
#
# This file is a modified version of the APACHECTL script.
# It will not be maintained wih respect to any changes made
# to that base script.
#
# WARNING
# -----
# This script is provided for educational purposes ONLY.
# It is merely an example of convenient way to identify a HTTPS.CONF
# file other than the standard file 'httpds.conf'
#
# The reader of this script is advised of his responsibility to
# ensure that the configuration file for the additional listener
# does what is expected and no more.
#
# For example, if the configuration file for an additional listener
# still has an include directive which reads the oracle_apache.conf
# file, then a second attempt to automatically start a Servlet Engine
# may be invoked, which may lead to undesirable side effects.
#
# Also, this script is a modified version of the utility 'apachectl'
# and will not be maintained with respect to future changes made to
# the script on which it is based.
#
# ENVIRONMENT VARIABLES
# -----
# The script is dependant on or it's behaviour modified by the
# following ENVIRONMENT VARIABLES:
#
#   ORACLE_HOME
#       should be set to the root directory of the iAS installation.
#
#   APCTL_CONFIG_ROOT
#       specifies a directory to be used as the root directory from
#       which all listener related configuration files and log files
#       will be located. If this environment variable is not set the
#       default of $ORACLE_HOME/Oracle/Oracle will be used.
#
#   APCTL_USE_SUBDIR
#       when set to TRUE indicates that the LISTENER NAME argument to
#       this script should be used to identify a subdirectory beneath
```

```

# the configuration area which contains a file httpds.conf for
# that listener, e.g. httpds_<LISTENER NAME>.conf
# When not set to TRUE indicates that the LISTENER NAME argument
# to this script should be used to determine the name of the
# configuration file, e.g. httpds_<LISTENER NAME>.conf
#
# APCTL_DIR_CAPS
# when set to TRUE specifies that sub-directory names below the
# APCTL_CONFIG_ROOT directory should be capitalised e.g.
# $APCTL_CONFIG_ROOT/Apache/a directory to be used as the root
# directory from which to get
#

%cp jserv.properties jserv_<jvm name>.properties

shell script

```
----- Code begins here -----
#!/bin/ksh

# =====
# SCRIPT: jservctl
#
# This script helps administor the Apache JSERV servers which are
# essentially a servlet engine running inside a JVM
#
# DISCLAIMER
# -----
# This script is provided by Oracle Support as an example of one
# methodology which streamlines the support and startup of multiple
# Apache Jserv servlet engines. Although this script has been tested
# within support for basic correctness, it is intended for educational
# purposes only and no support is provided for it's use.
#
# CONFIGURATION
# -----
# Before running this script you will need to make modifications to
# configure it so that it can find needed files in the locations where
# they are installed at your location.
#
# The approach and operation of this script is described in the
# CONFIGURATION OVERVIEW section. If you are using this script for the
# first time please read this section to gain a better understanding
# of how the script is intended to work. If you have already run the
# script successfully and are already somewhat familiar with how it
# works then the CONFIGURATION ROOT DIRECTORY section.
#
# SYNTAX
# -----
# jservctl start <jvm_name>
# jservctl stop <jvm_name>
# jservctl version <jvm_name>
# jservctl options <jvm_name>
# jservctl help
# jservctl -h
#
```

```

# where:
#
# <jvm_name> - indicates a naming convention used to identify the
#             correct targets for configuration and log files.
#
# CONFIGURATION OVERVIEW
# -----
# The script distinguishes between the following two areas within the
# installation heirarchy:
#
# (a) binaries, libraries and core configuration files
#     These are all expected to remain in the same location relative
#     to the ORACLE_HOME;
#
# (b) per instance configuration files
#     These are specific to one instance of the Apache listener
#     or specific to one instance of the Apache JServ Servlet Engine;
#
# The following sections discuss these concepts further and identify
# where the script expects to find key configuration files within the
# installation and configuration roadmaps respectively.
#
# (a) binaries, libraries and core configuration files
# -----
#     Only the configuration directory is assumed to have moved.
#     The following directories are all assumed to be in the same
#     position relative to the ORACLE_HOME directory:
#
#     ${ORACLE_HOME}
#     |- Apache
#         |- jdk
#         |- jsdk
#             |- lib
#                 |- jsdk.jar
#         |- jserv
#             |- libexec
#                 |- jsdk.jar
#         |- jdk
#
# (b) per instance configuration files
# -----
#     Although a default iAS installation locates these files within
#     distinct sub-directories which are located within the main
#     ORACLE_HOME these files are logically distinct and can safely
#     be located beneath a directory which is located completely
#     outside of the ORACLE_HOME.
#
#     It is also possible, to have these files owned by a different
#     UNIX user, provided that:
#
#     - the user owning the per instance configuration files has
#       sufficient file priviliges on the ORACLE_HOME, such as being
#       member of the same UNIX group;
#     - the user has set up the following environment variables with
#       values consistent with those in the user account which
#       installed the iAS software and owns the ORACLE_HOME:
#
#         ORACLE_HOME=<location of home for iAS binaries>
#         LD_LIBRARY_PATH=${ORACLE_HOME}/lib: <standard ld entries>
#         ORACLE_SID=<database sid>
#
#     NOTE: It is assumed that at least ORACLE_HOME and LD_LIBRARY_PATH
#           are set as indicated regardless of whether this is from
#           the environment of a newly created UNIX user or by
#           the user who owns the iAS installation. In the latter case
#           these UNIX environment variables should already be set
#           appropriately by default.
#
#     The location of the top directory used as the root of the
#     directory heirarchy under which all per instance configuration

```

```

# files are stored is specified by the CONFIG_ROOT parameter
# embedded within this script, as described in the section
# CONFIGURATION ROOT DIRECTORY below.
#
# CONFIGURATION ROOT DIRECTORY
# -----
# The script assumes that all configuration files are located in a
# fairly rigidly defined directory heirarchy located beneath a common
# directory as specified by the CONFIG_ROOT variable below.
#
# The following directory structure is assumed:
#
#   S{CONFIG_ROOT_DIR}
#   |
#   | - JSERV
#   |   |
#   |   | - ETC
#   |   |   |
#   |   |   | - j serv. conf
#   |   |   | - j serv_<j vm_name>. properties
#   |   |   |
#   |   |   | - LOGS
#   |   |   |   |
#   |   |   |   | - j vm_<j vm_name>. log
#   |   |   |
#   |   | - APACHE
#   |   |   |
#   |   |   | - CONF
#   |   |   |   |
#   |   |   |   | - httpds_<list_name>. conf
#   |   |   |   |
#   |   |   |   | - LOGS
#   |   |   |   |   |
#   |   |   |   |   | - httpds_<list_name>. pid
#   |   |   |   |   | - httpds_<list_name>_access_log
#   |   |   |   |   | - httpds_<list_name>_error_log
#
# CREATION OF A CONFIGURATION ROOT DIRECTORY
# -----
# The initial configuration root directory can be created by manually
# creating the directory structure described above and copying the
# default configuration files as a starting point for further
# modification.
#
# The default file equivalent of the files identified in the above
# roadmap would be found in a corresponding position within the
# $ORACLE_HOME/Apache directory tree, except that the directory
# names are not capitalized.
#

<http://myhost:myport/dms0/Spy?recurse=all&format=raw&name=/>

The screenshot shows a Microsoft Internet Explorer window with the address bar containing the URL <http://jweom:7777/dms0/Spy?recurse=all&format=raw&name=/>. The main content area displays the output of a DMSDUMP command, which is a raw text dump of Apache server statistics. The output includes sections for overall server statistics, request statistics, connection statistics, and module statistics. The statistics show various metrics such as internal redirect counts, number of modules, handle times, request times, and connection times.

```

6.9.2 Apache Jserv

Apache Jserv Module \

[1] Determine if the Apache HTTPD process is running and servicing requests for static HTML.

(a) From a browser, request the following URL:

```
http://<host>.<domain>:<port>/
```

(By default iAS is configured on port 7777)

(b) If the above step does not return a HTML page then check that the Apache HTTPD process is running:

```
% ps -ef|grep ${ORACLE_HOME}|grep httpd
```

(c) If the above returns no matches from the UNIX process table then:

- ensure that you are using the correct set of environment variables to administer the iAS product stack;

- attempt to start the Apache listener using:

```
'apachectl start';
```

- re-check the process table for httpd processes:

```
% ps -ef|grep ${ORACLE_HOME}|grep httpd
```

(d) If after the above steps the httpd process still does not show in the process table, run:

```
% apachectl configtest
```

and explore any warnings returned by reviewing and editing the listener configuration file:

```
${ORACLE_HOME}/Apache/Http/conf/httpd.conf
```

Continue correcting errors until the configtest output shows the following:

```
% apachectl configtest
```

```
Syntax OK
```

[2] Determine if the intended Servlet Engine is running.

(a) Run the following command:

```
% ps -ef|grep ${ORACLE_HOME}|grep 'org.apache.jserv'
```

NOTE: due to line length restrictions observed by the 'ps' command the output of the command may not show enough to match the full 'org.apache.jserv' specified as the grep pattern.

In the event that the above command fails on your system, try running:

```
% ps -ef|grep ${ORACLE_HOME}|grep
```

and scrutinizing the output for some left portion of 'java org.apache', before deciding whether or not there are any Servlet Engines running.

(b) If the 'ps' command reveals evidence that a Servlet Engine is running, check to ensure that it is the one that was expected, by looking at the status of the TCP/IP port on which that Servlet Engine will be looking for requests.

Each servlet engine listens for requests on the network interface and port identified by the 'bindaddress' and 'port' parameters within the 'jserv.properties' configuration file:

```
bindaddress=myhost.mydomain.com  
  
port=8007
```

Use the defined port number in the following 'netstat' command to see if there is a process LISTENING on that port:

```
% netstat -a|grep 18007  
sunburn.us.oracle.com.18007 *.* 0 0 0 0 LISTEN
```

Note which hostname is depicted in the first column to see if this is the fully qualified hostname or 'localhost', as show below:

```
% netstat -a|grep 18007  
localhost.18007 *.* 0 0 0 0 LISTEN
```

The first column should match the value of the 'bindaddress' directive specified in the 'jserv.properties' file.

NOTE: to allow this servlet engine to be referenced by multiple remote hosts the bindaddress parameter should be set to '*':

```
bindaddress=*
```

(c) If no process is listening on that port, then review the MOD_JSERV log file for warnings and errors which occurred while attempting to auto start the servlet engine.

The MOD_JSERV log file is identified by the 'ApJServLogFile' directive in 'jserv.conf'. By default this will be:

```
${ORACLE_HOME}/Apache/Jserv/logs/jserv.log
```

Review this file and attempt to resolve the errors identified in this file. For example, the following is a typical error which the port that the servlet engine would like to attach to is already in use:

```
[13/06/2000 14:23:58:528 EDT] ApacheJServ/1.1: Exception creating the server socket:  
java.net.BindException: Address already in use
```

[3] If the intended servlet engine is not running, but there are no errors in the MOD_JSERV log file, then identify from the log file whether any attempt was made to startup a Servlet Engine and confirm via the jserv.conf file whether MOD_JSERV is configured not to automatically start the servlet engine.

(a) Regardless of any specific message in the MOD_JSERV log about problems starting the servlet engine, diagnostic error messages are displayed each time MOD_JSERV attempts to start the servlet engine.

Look for the existence of log entries which include 'wrapper', such as the following:

[13/11/2000 16:15:56:110] (INFO) wrapper: Java VM is not responding (PID=7882)

Any entries of this nature confirm that an attempt was made to start the servlet engine.

(b) If there are no log entries to confirm that an attempt was made to start the servlet engine then:

- confirm that MOD_JSERV has not been configured to automatically start the Servlet Engine, by checking in the file:

\$ORACLE_HOME/Apache/Jserv/etc/jserv.conf

that the parameter 'ApJServManual' is set to On.

- Either:

(i) modify this parameter so that MOD_JSERV will automatically start the servlet engine:

ApJServManual=Off

--- OR ---

(ii) utilize a script to manually start the servlet engine, as described in:

Note:123533.1

"Example script to manually start the JVM for the

MOD_JSERV servlet engine"

[4] Configure the MOD_JSERV status page, to provide additional diagnostics through the eyes of the MOD_JSERV cartridge.

The MOD_JSERV cartridge provides an additional request handler 'jserv-status' which provides invaluable information about the status of MOD_JSERV and any servlet engine it is configured to access.

Since the low level information supplied by the 'jserv-status' handler could be taken advantage of by a would be hacker, it is by default disabled. To enable this information to be accessed by browser, the 'jserv.conf' file should be modified to uncomment the following configuration directive:

```
<Location /jserv/>  
    SetHandler jserv-status  
    order deny,allow  
    deny from all  
    allow from us.oracle.com  
</Location>
```

NOTE: to decrease concerns over reduced security the 'allow from' directive can be used to restrict access to:

- the hostname or ip address of a single PC in the network where the browser will be running;
 - the domain name of a group of machines where the browser will be allowed to run;
- set to 'localhost' to ensure that access is provided only to a browser running directly on the machine where the Apache Listener is running;

Once enabled, status information about MOD_JSERV and mapped servlet engines can be accessed via the URL:

`http://<host>.<domain>:<port>/jserv/`

This information should be checked for consistency with your expectation of what is defined in the configuration files. In the event that any of the settings do meet expectations, close scrutiny should be placed on the relevant configuration file to see if there are multiple directives for the same parameter such that the value supplied by the last directive in that file might be over writing the first.

6.9.3 Apache JServ Performance Tuning Point

iAS Apache JServ (Internal Server Error)

You have successfully installed iAS (release 1.0.x) and can access HTML files. But when trying to access any servlet (e.g. IsItWorking demo servlet which comes with iAS) you get:

Internal Server Error The server encountered an internal error or misconfiguration and was unable to complete your request.

Looking in mod_jserv.log (<ORACLE_HOME>/Apache/Jserv/logs),

you see following lines:

```
[date time] (EMERGENCY) ajp12: can not connect to host 127.0.0.1:8007
[date time] (EMERGENCY) ajp12: connection fail
[date time] (ERROR) an error returned handling request via protocol "ajpv12"
```

Solution Description

Open Apache JServ Configuration File "jserv.properties"

(<ORACLE_HOME>/Apache/Jserv/etc or <ORACLE_HOME>\Apache\Jserv\conf)

and check setting of wrapper.bin=

It has to point to existing JVM, e.g.:

```
wrapper.bin=/oracle/app/oracle/product/ias/Apache/jdk/bin/java
```

The following things were done to improve the situation:

The Network adapters were set to autoconf, which gave a boost of 500 Kb/s for second attempt requests. The Server-service was changed from FileServer to NetworkServer. The suggestions in the Oracle HTTP Performance guide have been followed, and TCP has been tuned the following way:

.

HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Tcpip\Parameters:

- DisableLargeSendOffload=0, enable large sends for TCP/IP.
- Parameters/MaxFreeTWTcbs=1098000, sets maximum number of TIME_WAIT tcbs to 1,098,000.
- MaxHashTableSize=0x10000, sets TCB hash table size to 65,536 entries, default 512.

- MaxSendSegments=0x1000, max TCP segments sent consecutively to a destination, default 64.
 - Parameters/MaxUserPort=0xffff, sets maximum open ports to 65534.
 - Parameters/NumTcbTablePartitions=64, sets number of independent TCB table segments, default 4.
 - Parameters/TcpTimedWaitDelay=60, sets TIME_WAIT parameter to 60 seconds (non-RFC 1122), default is 240.
- @ - Parameters/TcpWindowSize=65535, sets TCP send/receive window size, default 8192

Apache and modules tuning

JServ tuning

zone.properties => autoreload.classes = false, autoreload.file = false (default values are true)

jserv.conf => ApJServVMTimeout 60 (default value is 30)

PL/SQL tuning:

wdbsvr.app => Comment out the line debugModules = all,
Set "reuse = yes" in all the database entries

Stress Test (EMERGENCY) ajp12: can not connect to host 127.0.0.1:8007

1. (EMERGENCY) ajp12: can not connect to host 127.0.0.1:8007
2. (EMERGENCY) ajp12: connection fail

Problem Description

When a HTTP client submits a request to Servlet engine, the request is dispatched from mod_jserv to the JServ Java runtime. mod_jserv is loaded in httpd and httpds. In iAS, it is statically linked in the listener. Either way, mod_jserv communicates with JServ Java runtime via Ajp protocol. By default, the JServ Java runtime has only 5 outstanding listening sockets. If there is no outstanding listen sockets in the JServ Java runtime, mod_jserv would log the following message and won't retry by default:

(EMERGENCY) ajp12: can not connect to host 127.0.0.1:8007

(EMERGENCY) ajp12: connection fail

Solution Description

To enable the retry mechanism in ajpv12_handler, the user can specify an un-documented property in jserv.conf:

```
# Retry 30 times
```

ApJServRetryAttempts 30

Explanation

For each retry, ajpv12_handler sleeps for 1 second (hard code) and logs "ajp12: can not connect to ...". After n tetries, if mod_jserv still cannot connect to JServ Java runtime, then it will log the following message:

```
ajp12: connection fail
```

By increasing the value of ApJServRetryAttempts in jserv.log, mod_jserv can retry connecting to the JServ runtime under heavy load. Hence, it won't log "ajp12: connection fail" message. However, it would still log the "ajp12: can not connect to host ..." message for each retry.

Further settings

For Java JServ runtime, you can also increase the number of listen sockets by adding the following properties in jserv.properties:

```
# Number of listen sockets
```

security.backlog=50

The maximum number of socket connections JServ may handle simultaneously. Makesure the OS has enough file descriptors to allow this number:

```
#Max number of socket connections
```

security.maxConnections=100

6.9.5 9iAS startJserv.sh

Oracle 9iAS 1.0.2.1	Apache Jserv	jserv.conf
ApJServManual off	<ORACLE_HOME>/Apache/Apache/bin	startJserv.sh

        this.file = file;
    }

    public void run() {
        try {

            OutputStream to_file;
            to_file = new FileOutputStream(file);
            URL url = new URL(url1);
            String protocol = url.getProtocol();
            if (!protocol.equals("http"))
                throw new IllegalArgumentException("URL must use 'http:' protocol");
            String host = url.getHost();
            int port = url.getPort();
            if (port == -1) port = 80;
            String filename = url.getFile();
            Socket socket = new Socket(host, port);
            InputStream from_server = socket.getInputStream();
            PrintWriter to_server =
                new PrintWriter(new OutputStreamWriter(socket.getOutputStream()));

            to_server.println("GET " + filename + " HTTP/1.0\n");
            to_server.flush();

            byte[] buffer = new byte[4096];
            int bytes_read;
            while((bytes_read = from_server.read(buffer)) != -1)
                to_file.write(buffer, 0, bytes_read);

            socket.close();
            to_file.close();
        }
        catch (Exception e)
            System.err.println(e);
    }

    public static void main(String[] args) {
        if ((args.length != 1) && (args.length != 3)) {
            System.out.println("Wrong number of arguments !! Syntax is java StressTest url filename
threads");
            System.exit(0);
        }
        for (int i = 0; i < Integer.parseInt(args[2]) ; i++) {
            StressTest t = new StressTest(args[0] ,args[1]+i);
            System.out.println("Firing Thread " +i);
            t.start();
        }
    }
}

```

Usage : java StressTest http://bldel56.in.oracle.com/servlet/TestConnection dd.txt 5

This creates text files as dd.txt0 , dd.txt1 ... dd.txt5. You can open the files in a text editor for checking whether the request is successful or not.

How To Test:

=====

1. Invoke sql*plus and issue the query after starting the servlet engine.

select sid , serial#, username , program from v\$session where program like 'JDBC%';

You should see 2 rows after loading the firstservlet.

2. java StressTest http://bldel56.in.oracle.com/servlet/TestConnection dd.txt 2

3. Run the query from sql*plus select sid , serial#, username , program from v\$session where program like 'JDBC%';

You should see two rows.

4. java StressTest http://bldel56.in.oracle.com/servlet/TestConnection dd.txt 4

5. Run the query from sql*plus select sid , serial#, username , program from v\$session where program like 'JDBC%';

You should see four rows.

6. java StressTest http://bldel56.in.oracle.com/servlet/TestConnection dd.txt 6

7. Run the query from sql*plus select sid , serial#, username , program from v\$session where program like 'JDBC%';

You should see 6 rows for some time once the servlet execution is finished the connection should be 5 as we set the max connections as 5.

6.9.7 Servlet

Servlet Life-Cycle

PURPOSE

The purpose of this article is to explain life-cycle of servlets and provide an example of Java servlet that handles concurrent client requests, manages threads and resources correctly and outputs the most often used HTTP parameters.

SCOPE & APPLICATION

This bulletin is useful for Java Developers who would like to understand how life-cycle of servlets and threads are managed by servlet engines, and what request properties and HTTP parameters are most often utilized in servlets.

LIFE-CYCLE OF SERVLETS

A servlet is a small Java program that runs within a context of a Web Server. Servlets receive and respond to requests from clients, usually across HTTP protocol.

Servlet life-cycle is separated in three different stages:

1. Initialization
2. Execution
3. Destruction

Life-cycle methods that belong to these stages are specified by the `javax.servlet.Servlet` interface, which is implemented directly or indirectly by all servlets. These methods are called at specific times by the servlet engine in a particular order during a servlet's life-cycle.

1. Initialization

The `init()` method of a servlet is called when a servlet is initialized and placed into service. The servlet engine calls this method exactly once for each servlet. The servlet will not be able to handle any requests until the `init()` method has completed successfully. The `ServletConfig` object passed by the servlet engine to a servlet represents the configuration information and contains initialization parameters and a reference to the `ServletContext` object, which gives the servlet information about the server environment. The following sample `init()` methods shows how to use `ServletConfig` and `ServletContext` objects to get servlet initialization parameters from the servlet engine and save them for further processing.

```
ServletConfig servletConfig;
ServletContext servletContext;
Hashtable servletParameters = new Hashtable();

public void init(ServletConfig servletConfig) throws ServletException
{ String st;

    super.init(servletConfig);
    this.servletConfig = servletConfig;
    this.servletContext = servletConfig.getServletContext();
    servletContext.log(servletInstanceNumber+". LifeCycleServlet: init");

    for(Enumeration e = servletConfig.getInitParameterNames(); e.hasMoreElements();)
    { st=e.nextElement().toString();
      servletParameters.put(st,servletConfig.getInitParameter(st));
    }
}
```

2. Execution

The `service()` method carries out a single request from the client. Basically two methods, `doGet()` and `doPost()` are to be used to receive requests from clients and send response to back. Either one or both of these methods can be defined and used as an entry point in a servlet. The servlet engine receives all request parameters that are used to construct a `ServletRequest` object. This object is used by the servlet to gather all needed information about the request made by the client such as the client's IP address, the port through which the request came in and many other interesting parameters that you can use in servlets programming. The servlet uses the `ServletResponse` object to return output to the client. The `service()` method is called multiple times to execute the servlet's logic.

3. Destruction

When a servlet application is being shutdown, the `destroy()` method is called to cleanup any resources allocated during initialization. No other method of the servlet will be executed before `destroy()` method is called after shutdown. This method will be called exactly once and waits until all working threads finish its operation.

Threads

Servlets typically run inside multi-threaded servlet engines such as Apache/Jserv bundled with Oracle9i Application Server, which can handle multiple service requests concurrently. Each instance of a servlet can be given multiple threads of execution. The servlet must handle concurrent requests and synchronize access to shared resources. The example below shows how to manage threads and resources within servlets.

TOOLS REQUIRED

To develop servlets for any servlet engine, you will need a compiler, a debugger, and other tools needed for servlet development. Oracle's JDeveloper and Sun's JDK and JSDK are tools that can be used when developing servlets. This program was created with Oracle JDeveloper 3.1.1.2 using JDK 1.2.2 and tested with Oracle HTTP Server (Apache/Jserv) servlet engine which is part of Oracle9i Application Server.

EXAMPLE

This example servlet logs which method is being called by the servlet engine during the servlet's life-cycle, displays request properties and initialization parameters, and scores the number of threads within the service method. The service is delayed by 10 seconds so that we could try and examine how the servlet behaves, when it must serve a new request within this time of period.

```
import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class LifeCycleServlet extends HttpServlet
{
    static int servletInstanceCounter = 0;
    int servletInstanceNumber = ++servletInstanceCounter;
    int requestNumber;

    ServletConfig servletConfig;
    ServletContext servletContext;
    Hashtable servletParameters = new Hashtable();

    /* Initialize global variables */
    public void init(ServletConfig servletConfig) throws ServletException
    { String st;

        super.init(servletConfig);
        this.servletConfig = servletConfig;
        this.servletContext = servletConfig.getServletContext();
        servletContext.log(servletInstanceNumber+". LifeCycleServlet: init");

        for(Enumeration e = servletConfig.getInitParameterNames(); e.hasMoreElements(); )
        { st=e.nextElement().toString();
```

```

        servletParameters.put(st,servletConfig.getInitParameter(st));
    }
}

private int threadCounter;

private synchronized void threadStart()
{ threadCounter++; }

private synchronized void threadStop()
{ threadCounter--;
  if(threadCounter == 0 && isServletDestroyed()) notifyAll(); }

private synchronized int getThreadCounter()
{ return(threadCounter); }

private boolean servletDestroyed;

private synchronized boolean isServletDestroyed()
{ return(servletDestroyed); }

private synchronized void servletDestroy(boolean b)
{ servletDestroyed = b;}

public synchronized void destroy()
{ servletDestroy(true);
  while(getThreadCounter(>0)
  try { wait(); } catch(InterruptedException e) {}
  servletContext.log(servletInstanceNumber+". LifecycleServlet: destroy");
}

/* Process the HTTP Get request */
public void doGet(HttpServletRequest request, HttpServletResponse response) throws

6.9.8 JDBC

Servlet **JDBC 2.0 Connection Pool / Cache**

Overview

This article contains an example of how to implement a cache of pooled connections in a Servlet in the middle tier. It explains the Connection Pooling and Connection Caching implementations of the Oracle JDBC 2.0 driver provided by Oracle with an 8.1.6 database.

The JDBC 2.0 implementation provides interfaces for Connection Pooling, but does not implement these interfaces itself. They must be implemented by the JDBC 2.0 vendor to provide the Connection Pooling functionality.

The `javax.sql.ConnectionPoolDataSource` interface outlines the standard functionality of connection pool data sources, which are factories for pooled connections. Oracle JDBC 2.0 implements the `ConnectionPoolDataSource` interface with the `oracle.jdbc.pool.OracleConnectionPoolDataSource` class.

Pooled Connection

A pooled connection instance is an instance of a class that implements the standard `javax.sql.PooledConnection` interface. The `getConnection()` method specified by this interface returns a logical connection instance that acts as a temporary handle to the physical connection, as opposed to encapsulating the physical connection, as does a non-pooling connection instance.

Oracle JDBC 2.0 implements the Pooled Connection interface with the `oracle.jdbc.pool.OraclePooledConnection` class. Each time a pooled connection instance `getConnection()` method is called, it returns a new connection instance that exhibits the default behavior, and closes any previous connection instance that still exists, and had been returned by the same pooled connection instance.

Connection Cache

A Connection Cache is built on top of Connection Pooling and is one more level of abstraction. Connection Pooling as such is not always useful and powerful. It provides the foundation and infrastructure needed to implement an effective Connection Cache. Unless the application is simple, it would need a Cache in most cases.

JDBC 2.0 does not mandate a Connection Cache to be implemented by the JDBC 2.0 vendor. But Oracle has implemented a connection cache by providing a class `oracle.jdbc.pool.OracleConnectionCacheImpl`. The application requests a connection through the `getConnection()` method of the connection cache instance.

The `OracleConnectionCacheImpl` class includes a maximum cache size that can be set using the `setMaxLimit`. The default value is 1.

The OracleConnectionCacheImpl class supports two schemes, known as cache schemes, for situations where the application has requested a connection, all existing pooled connections are in use, and the maximum number of pooled connections in the cache has been reached.

dynamic

In the dynamic scheme, which is the default, new pooled connections can be created above and beyond the maximum limit, but each one is automatically closed and freed as soon the logical connection instance that it provided is no longer in use.

fixed with no wait

In the 'fixed with no wait' scheme, the maximum limit cannot be exceeded. Requests for connections when the maximum has already been reached return null.

Set the cache scheme by invoking the setCacheScheme() method of the OracleConnectionCacheImpl instance. Use one of the following class static constants as input:

DYNAMIC_SCHEME

FIXED_RETURN_NULL_SCHEME

For Connection Pooling and Connection Caching, classes12.zip and jndi.zip must be included in the classpath. Package oracle.jdbc.pool must be imported which includes all the classes of for Connection Pooling and Connection Caching.

Program Notes

In the example below, a servlet creates a Cache of pooled connections using the cache scheme FIXED_RETURN_NULL_SCHEME. The maximum number of connections is three. More than three connections at a time are not possible. Once the connection is closed, it is returned back to the cache and can be reused.

SAMPLE CODE

```
import java.io.*;
import java.sql.*;
import javax.servlet.*;
import javax.servlet.http.*;
import javax.sql.*;
import oracle.jdbc.driver.*;
import oracle.jdbc.pool.*;

public class Pooljdbc2 extends HttpServlet{
```

```

private OracleConnectionPoolDataSource ocpds;
private OracleConnectionCacheImpl ods;

public void init(ServletConfig config) throws ServletException {
    super.init(config);
    try {
        ocpds =new OracleConnectionPoolDataSource();
        ocpds.setURL("jdbc:oracle:thin:@blde152:1522:v816");

        // ocpds.setUser("scott");
        // ocpds.setPassword("tiger");

        // Associate it with the Cache
        ods = new OracleConnectionCacheImpl(ocpds);

        // Set the Max Limit
        ods.setMaxLimit (3);

        // Set the Scheme
        ods.setCacheScheme (OracleConnectionCacheImpl.FIXED_RETURN_NULL_SCHEME);
    }
    catch (Exception e) {
        throw new UnavailableException(this, "Couldn't create connection pool");
    }
}

public void doGet(HttpServletRequest req, HttpServletResponse res)
    throws ServletException, IOException {
    Connection con = null;
    res.setContentType("text/plain");
    PrintWriter out = res.getWriter();
    out.println("Updating salary");

    try {
        con = ods.getConnection("scott","tiger");

        // Turn on transactions
        con.setAutoCommit(false);

        Statement stmt = con.createStatement();
        stmt.executeUpdate("UPDATE EMPBIG SET SAL = (SAL - 10) ");
        stmt.executeUpdate("UPDATE EMPBIG SET SAL = (SAL + 10) ");
        con.commit();
        out.println("Salary updated");
        con.close();
    }
    catch (Exception e) {

        // Any error is grounds for rollback
        try
            con.rollback();
        }
        catch (Exception ignored) { }
        out.println("No more connections available, try later");
    }
}

public void destroy() {
    try
        ods.close();
}

```

```
    }
    catch (Exception ignored) { }
  }
}
```

Explanation

If the classpath is too big may cause the problem i.e the JVM may not get invoked.

Creating a global database connection pool in servlets

PURPOSE

This article explains how to create a global connection pool which will be accessed by all other servlets.

One of the most expensive database operations is establishing a connection to the database. If the database and servlet engine are located at two geographical locations the connection might take much longer.

It is beneficial to allocate certain pre-connected sessions to the database and use them when it is required.

The 8.1.6 JDBC drivers supports a connection pooling.

This article uses the connection pooling using Oracle 8.1.6 JDBC drivers.

The connection pooling can be divided in three different types in a servlet.

1. Establishing a connection in the init section.

The problem with this method, is that if you have say 200 servlets which uses the database then there will be 200 connections to be opened on the DB server.

A common mistake is to create a single connection in the initialization section (run only once) of a servlet to be reused for each invocation of the servlet, avoiding the startup timing requirement.

While there is nothing to prevent this from being implemented and it usually functions for a

single user, it will wreak havoc once placed under a load where concurrent "hits" cause two or more threads to run at the same time.

2. Establishing a connection in the doGet method or doPost method and disconnecting at the end of the methods.

This takes lot of time. Every time the servlet is invoked it has to make a connection and disconnect at the end.

3. Using a global database connection pooling.

For example, if you had 200 servlets and a 50 user license for your database, you might want to set up a global shared pool with a max pool size of 50 and a min pool size of 20.

Initially there will be 20 connection to the database. Once the load is increased to say > 20 then additional connections will be made to the database up to 50.

The first servlet is a dummy servlet which makes some initial connection to the database.

The first servlet need to be loaded by the servlet engine during the startup of the servlet engine.

The other servlets will make use of the the connections created by this servlet.

The StressTest.java is a simple java application which simulates the simultaneous load on the servlet engine.

StressTest.java

```
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;
import java.util.*;
import java.sql.*;
import oracle.jdbc.driver.*;
import oracle.jdbc.pool.*;

public class InitConnection extends HttpServlet {

    public static final String TITLE = "Yes, It's working!";
    public Connection conn = null;
    public OracleConnectionCacheImpl ods =null;

    public void init (ServletConfig config) throws ServletException
    {
        super.init(config);
        try {
            ods = new OracleConnectionCacheImpl();
            ods.setURL("jdbc:oracle:thin:@varuna:1521:V816");
            ods.setUser("scott");
            ods.setPassword("tiger");
            System.out.println("Ravi");
            // Set the Max Limit
            ods.setMinLimit(2);
            ods.setMaxLimit (5);
        }
    }
}
```

```

        Connection conn = null;
    }
    catch (Exception e) {
        e.printStackTrace();
    }
}

public void service (HttpServletRequest request, HttpServletResponse response)
throws ServletException, IOException
{
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    String server = getServletConfig().getServletContext().getServerInfo();
    // write the data
    String value = null;
    value = request.getHeader("User-Agent");
    int i = value.indexOf("MSIE");
    if (i == -1 )    out.println("<P> The browser is Netscape");
    else
        out.println("<P> The browser is MS IE");
    }
}

```

TestConnection.java

```

import java.io.*;
import java.util.*;
import javax.servlet.*;
import javax.servlet.http.*;
import java.sql.*;
import oracle.jdbc.driver.*;
import oracle.jdbc.pool.*;

public class TestConnection extends HttpServlet {

    public void doGet(HttpServletRequest req, HttpServletResponse res)
    throws ServletException, IOException {
        res.setContentType("text/html");
        PrintWriter out = res.getWriter();

        ServletContext context = getServletContext();
        Servlet name = context.getServlet("InitConnection");
        InitConnection t1 = (InitConnection) name;

        try {
            Connection conn = t1.ods.getConnection();
            Statement stmt = conn.createStatement ();
            ResultSet rset = stmt.executeQuery ("select sid , serial#, username ,
program from v$session where auid = userenv('SESSIONID') ");
            Thread.sleep(10000); // Wait for some time for holding the connection
            while (rset.next () {
                out.println ("<BR>" +rset.getString (1) +"...." +rset.getString
(2)+"...." +rset.getString (3)+"...." +rset.getString (4));
            }
            rset.close();
            stmt.close();
            conn.close();
        } catch (Exception e) {e.printStackTrace();
        }
    }
}

```

}

How to use JDeveloper's Connection Manager in servlets

The purpose of this article is to show how to use Oracle Connection Manager on the middle-tier such as Oracle9i Application Server by providing an example of a Java servlet that uses JDBC connection requested from Connection Manager to query records from the database and outputs the most often used Connection Manager properties.

SCOPE & APPLICATION

This bulletin is useful for Java Developers who would like to leverage Oracle Connection Manager in servlets. It also provides necessary steps to deploy the example servlet and Connection Manager to Oracle9i Application Server.

WHAT IS CONNECTION MANAGER

Oracle Connection Manager bundled with Oracle JDeveloper and Oracle9i Application Server is responsible for creating and managing JDBC-based connections. It allows connection objects to be shared without requiring individual objects to explicitly know about each other. Individual objects are able to request connections by name from Connection Manager, where possible, Connection Manager will reuse existing connection objects that have already been created earlier.

Connection Manager also allows users to request a "private", non-shared connection. This allows users with special needs access to their own connection object, without worrying about resource contention with other unknown objects.

The classes and interfaces of Oracle Connection Manager are packaged into a single package namely oracle.jdeveloper.cm.

Major classes and their functionalities:

- ConnectionManager: responsible for creating and managing JDBC-based connections.
- ConnectionWrapper: generic object which is returned by ConnectionManager.
- ConnectionDescriptor: used to describe connections.

PROMPTING BEHAVIOR:

By default, Connection Manager will always prompt for username and password. However, this behaviour may not always be appropriate as in the case of servlets. The getConnection() methods allow for customization of prompting behaviour to prompt for information at all. The ConnectInfoPrompter describes how Connection Manager expects to be able to prompt users for security information.

To alter Connection Manager's prompting behaviour not to prompt for information at all, use the following statement:

```
cw = cm.getConnection("Connection1",(ConnectInfoPrompter) null);
```

HOW TO INITIALIZE CONNECTION MANAGER:

The `init()` method of a servlet is called when a servlet is initialized and placed into service. The servlet engine calls this method exactly once for each servlet. This is an ideal place to get a reference to a `ConnectionManager` instance.

```
public void init(ServletConfig config) throws ServletException
{
    super.init(config);
    cm = ConnectionManager.getInstance();
}
```

HOW TO DEPLOY CONNECTION MANAGER UNDER iAS

The 'connectionmanager.zip' contains all of the classes and interfaces required by Oracle Connection Manager. It is to be found in the `$IAS_HOME/Apache/BC4J/lib` directory. The 'connectionmanager.zip' must be available on the CLASSPATH. The 'jserv.properties' file contains the following CLASSPATH related entry for Connection Manager by default:

```
wrapper.classpath=/disk1/app/oracle/product/9iAS/Apache/BC4J/lib/connectionmanager.zip
```

The connection information is stored in a properties file namely 'connections.properties' by default. The JDeveloper IDE automatically creates this file as part of the deployment process. Upon request, Connection Manager reads the information from the properties file in order to instantiate a connection. The physical location of the properties file must be added to the CLASSPATH of Apache/JServ. To do this open the 'jserv.properties' file in the `$IAS_HOME/Apache/Jserv/etc` directory for editing and add a new 'wrapper.classpath' entry to point to the 'connections.properties' file where it is physically located. For example:

```
wrapper.classpath=/disk1/app/web/servlet
```

Warning: Be sure that another jar file that contains the 'connections.properties' is not before this classpath specification!

The 'connections.properties' file managed by JDeveloper might look like as follows:

```
CM_NumConnections=1
CM_Connection1=password\=manager\r,defaultBatchValue\=1\r,ConnectionType\=JDBC\r,
ConnectionName\=O8i_JDBC_THIN_T817_SCOTT\r,user\=scott\r,DeployPassword\=true\r,
URL\=jdbc\:\:oracle\:\:thin\:\:@www.company.com\:\:1521\:\:ORCL\r,
remarksReporting\=false\r,JdbcDriver\=oracle.jdbc.driver.OracleDriver\r,
defaultRowPrefetch\=10\r,Role\=Normal
```

TOOLS REQUIRED

To develop servlets for any servlet engine, you will need a compiler, a debugger, and other tools needed for servlet development. Oracle's JDeveloper and Sun's JDK and JSDK are tools that can be used when developing servlets. This program was created with Oracle JDeveloper 3.2 using JDK 1.2.2 and tested with Oracle HTTP Server (Apache/Jserv) servlet engine which is part of Oracle9i Application Server.

EXAMPLE

This example servlet shows how to use Oracle Connection Manager in servlets and displays the most often used Connection Manager parameters.

```
import javax.servlet.*;
import javax.servlet.http.*;

import java.io.*;
import java.util.*;
import java.sql.*;
import oracle.jdbc.driver.*;

import oracle.jdeveloper.cm.*;
import oracle.jdeveloper.cm.ConnectionManager;
import oracle.jdeveloper.cm.ConnectionDescriptor;
import oracle.jdeveloper.cm.ConnectInformationDialog;

public class ConnectionManagerServlet extends HttpServlet
{

    private Connection conn;
    private ConnectionManager cm;
    private ConnectionWrapper cw;
    private ConnectionDescriptor cd;

    private Statement stmt;
    private ResultSet rset;

    public void init(ServletConfig config) throws ServletException
    {
        super.init(config);
        cm = ConnectionManager.getInstance();
    }

    public void destroy()
    {
        super.destroy();
        cd = null; cw = null; cm = null;
    }

    public void doGet(HttpServletRequest request, HttpServletResponse response) throws
ServletException, IOException
    {
        response.setContentType("text/html");
        OutputStreamWriter osw = new OutputStreamWriter(response.getOutputStream());
        PrintWriter out = new PrintWriter (response.getOutputStream());
        out.println("<html>");
    }
}
```

```

out.println("<head><title>ConnectionManagerServlet</title></head>");

try
{
// Replace ConnectionName with value from connections.properties file
cw = cm.getConnection("ConnectionName",(ConnectInfoPrompter) null);
conn = (Connection) cw;
cd = cw.getDescriptor();

out.println("<PRE><STRONG>Connection Manager parameters</STRONG>");
out.println();
out.println("Connection name: "+cd.getConnectionName());
out.println("Connection type: "+cd.getConnectionType());
out.println("JDBC Driver....: "+cd.getJdbcDriver());
out.println("Deployed URL...: "+cd.getURL());
out.println("Username.....: "+cd.getUsername());
out.println("Password.....: "+cd.getPassword());
out.println();

stmt = conn.createStatement();
rset = stmt.executeQuery("SELECT ENAME, SAL FROM EMP");

while(rset.next())
{ out.print(rset.getString(1)+" - ");
out.print(rset.getDouble(2));
out.println(); }

} catch (CMException e) { e.printStackTrace(); }
catch (SQLException e) { e.printStackTrace(); }
finally
{ if(rset != null)
{ try { rset.close(); }
catch (SQLException e) { e.printStackTrace(); }
}
if(stmt != null)
{ try { stmt.close(); }
catch (SQLException e) { e.printStackTrace(); }
}
if(conn != null)
{ try { conn.close(); }
catch (SQLException e) { e.printStackTrace(); }
}
}

out.println("</body></html>");
out.close();
}

public void doPost(HttpServletRequest request, HttpServletResponse response) throws
ServletException, IOException
{
doGet(request,response);
}

public String getServletInfo()
{
return "ConnectionManagerServlet Information";
}
}

```

Web Cache

Database Cache

Object Caching Service for Java (OCS4J)

9.1 Web Cache

9.1.1 Web Cache

0. Oracle Web Cache [upgrade](#) [가 가](#) [otn](#) [version](#) [download](#)

1. Oracle Web Cache Manager

`% webcachectl start`

Or, from the Services Control Panel on NT.

2. Web Browser [Oracle Web cache administration page](#)

`http://hostname.domainnameOfWebCacheMachine:4000/webcacheadmin`

`(administrator/administrator)`

For Oracle Web Cache to act as a virtual server for a website, configure Oracle Web Cache with information about the website, including the host names of the application Web servers. In addition, specify a listening port from which Oracle Web Cache can receive browser requests.

To configure Oracle Web Cache with Web site information:

3. Configure the application Web servers for the Web site:

a. In the navigator pane,

select Administering Web Sites > Application Web Servers.

The Application Web Servers page appears in the right pane.

b. In the Application Web Servers page, choose Add.

The Edit/Create Application Web Server page dialog box appears.

c. In the Hostname field, enter the hostname of the application Web server.

d. In the Port field, enter the listening port from which the application Web server will receive Oracle Web Cache requests.

e. In the Capacity field, enter the number of concurrent connections that the application Web server can sustain.

Optionally, configure an additional listening port from which Oracle Web Cache will receive browser requests. Oracle Web Cache listens on port 1100 by default. It may be necessary to add an additional listening port if you want to assign Oracle Web Cache a port that an application Web server was previously listening on.

a. In the navigator pane, select Administering Web Sites >

Oracle Web Cache Listen Ports.

The Oracle Web Cache Listen Ports page appears in the right pane.

b. In the Oracle Web Cache Listen Ports page, choose Add.

The Edit/Create Oracle Web Cache Listen Ports page dialog box appears.

c. In the Oracle Web Cache IP Address field, enter the IP address of the computer running Oracle Web Cache.

d. In the Oracle Web Cache Listen Port field, enter the listening port from which Oracle Web Cache will receive Web browser requests for the Web site. Ensure this port number is not already in use.

e. Choose Submit.

In the Oracle Web Cache Manager main window, choose Apply Changes, and stop and start webcache with the commands "webcachectl stop" and "webcachectl start".

(or from the Services Control Panel on NT)

Point your browser to the URL to WebCache port...

`http://hostname.domainnameOfWebCacheMachine:1100/`

Or, if configured WebCache on port 80...

`http://hostname.domainnameOfWebCacheMachine/`

...and you should see the index.html of your site.

Note: If on the same machine, you cannot have the webcache and your website on the same port(s), otherwise the second one will fail to start. Setting the Web Cache to port 80, and pointing it to a webserver that is listening on a different port not in use is the most common setup.

9.1.2 Troubleshooting

WEBCACHE LISTENER CAN NOT START WHEN ORACLE_HOME STARTS

When starting the webcache listeners using webcachectl start, I get the following errors:

```
$ ./webcachectl start
```

Oracle Web Cache, Version 2.0.0.1.0

@ Copyright: Oracle Corporation, 1999-2001

Admin Server failed to start

Oracle Web Cache couldn't start.

Solution Description

Create a symbolic link e.g. /webcache to point to the root directory of your ORACLE_HOME

e.g. /ora1

```
ln -s /ora1 /webcache
```

Now open the webcachectl script and change the ORACLE_HOME entry to point to the path starting with the symbolic link (e.g. /webcache/app/oracle/product/webcache)

After doing so the webcache daemon can be started using:

```
$ ./webcachectl start
```

Explanation

There is a bug 1849408 which causes the webcache daemon not to start when the ORACLE_HOME starts with /ora

Run the WebCache listener on a port below 1024.

Intended for customers and support analysts who are attempting to run the WebCache listener on a port below 1024.

Oracle Web Cache Failed to Initialize

You have completed a new installation of Oracle WebCache on a Unix based operating system and configured your WebCache listener to run on a port below 1024. When attempting to start the WebCache you receive an error:

Error: Oracle WebCache Cache failed to initialize

Error: The server could not initialize.

Since you are attempting to run a process on a port below 1024, the process requires root privileges. The root.sh script that comes with Oracle 9iAS does not set these privileges for the WebCache listener. To fix the problem use the following steps:

- 1). Access your webcache administration page (by default on port 4000) and change the "process identity" to nobody/nobody.
- 2) Login to your Unix server as the user who installed WebCache and su root.
- 3) chown root <Webcache Home Directory>/webcache/bin/webcached
- 4) chmod a+s <Webcache Home Directory>/webcache/bin/webcached
- 5) exit
- 6) webcachectl start.

9.2 Database Cache

Installing Oracle Database Cache

The installation of the Oracle Database Cache involves following stages:

1. Preparing the Origin Database
2. Installing the Oracle8i Cache
3. Installing the Oracle8i Cache Manager for OEM

1. Preparing the Origin Database:

The origin database for the Oracle database cache should be decided before installing the Oracle database cache software. This is mandatory because, the Oracle database cache software installation creates the necessary tnsnames.ora files based on this.

a. Creating Password file for the origin database

+ Shut down the origin database

+ Set the following parameter in the init.ora file:

```
remote_login_passwordfile=Exclusive
```

or

```
remote_login_passwordfile=Shared
```

+ Create the password file in the origin database's \$ORACLE_HOME/dbs directory as follows:

```
$orapwd file=orapwSID password=passwd entries=5
```

+ Startup the Origin database

b. Setting up External Listener

Add the following listener to your listener.ora file. The only change to be done on this is the oracle_home.

```
External_procedure_listener=  
  (address_list=  
    (address= (protocol=ipc) (key=extproc_key))  
  )
```

```
Sid_list_external_procedure_listener=  
  (sid_list=  
    (sid_desc=  
      (sid_name=extproc_agent)  
      (oracle_home=/u01/app/oracle/product/8.1.6)
```

```
## Enter your Oracle home here
                                (program=extproc)
                                )
                                )
```

Start this listener:

```
$ lsnrctl start external_procedure_listener
```

```
LSNRCTL for Solaris: Version 8.1.6.0.0 - Production on 10-AUG-2000 14:48:21
```

```
(c) Copyright 1998, 1999, Oracle Corporation. All rights reserved.
```

```
Starting /u01/app/oracle/product/8.1.6/bin/tnslsnr: please wait...
```

```
TNSLSNR for Solaris: Version 8.1.6.0.0 - Production
System parameter file is /u01/app/oracle/product/8.1.6/network/admin/listea
Log messages written to /u01/app/oracle/product/8.1.6/network/log/externalg
Listening on: (DESCRIPTION=(ADDRESS=(PROTOCOL=ipc)(KEY=extproc_key)))
```

```
Connecting to (address=(protocol=ipc)(key=extproc_key))
```

```
STATUS of the LISTENER
```

```
-----
Alias                external_procedure_listener
Version              TNSLSNR for Solaris: Version 8.1.6.0.0 - Production
Start Date           10-AUG-2000 14:48:21
Uptime               0 days 0 hr. 0 min. 0 sec
Trace Level          off
Security             OFF
SNMP                 OFF
Listener Parameter File /u01/app/oracle/product/8.1.6/network/admin/lista
Listener Log File    /u01/app/oracle/product/8.1.6/network/log/externg
Services Summary...
  extproc_agent      has 1 service handler(s)
The command completed successfully
$
```

Also startup the normal listener listening on a port.

Add the following entry to the tnsnames.ora file to connect to the above listener:

```
extproc_connection_data=
  (description=
    (address=(protocol=ipc) (key=extproc_key))
    (connect_data=(sid=extproc_agent))
  )
```

Check that this connect string is fine by using tns ping utility:

```
$ tnsping extproc_connection_data
```

TNS Ping Utility for Solaris: Version 8.1.6.0.0 - Production on 11-AUG-2000 11:5

(c) Copyright 1997 Oracle Corporation. All rights reserved.

```
Attempting to contact (address=(protocol=ipc)(key=extproc_key))
OK (100 msec)
```

c. Granting Necessary Privileges to a DBA User

The Oracle8i Cache Configuration Assistant requires an Oracle user with SYSDBA user for the operations on the the origin database. SYS is the default user used by the configuration assistant and hence make sure you that SYS has SYSDBA privilege.

```
$ svrmgrl
```

Statement processed.
SVRMGR>
```

2. Installing the Oracle Database Cache

a. Installing the Cache Software

The software has to be installed from the Oracle8i Cache media. The current version 1.0 is bundled with the Internet Application Server 1.0.0.0.0.

Invoke the installer from the Oracle iAS CD. Note you need to have XTerm environment to invoke the installer. There is no character mode to run the installer.

```
./runInstaller
```

In the Installation Type window, select Enterprise Edition to install Oracle8i Cache, Oracle Jserver, Oracle HTTP Server. You cannot install Oracle8I Cache alone in this version. The total space required for this option is 3.08Gb.

Also make sure you have at least 500Mb temp space, else set the environment variable TMP to point to a directory which has more than 500Mb space.

During the installation, the installer asks for the origin database details like

- Machine name
- Database name
- the listener port number

These data are used to configure the tnsnames.ora file of the cache machine.

The tnsnames.ora created would be as follows:

```
ora_ocache =
  (DESCRIPTION =
    (ADDRESS_LIST =
      (ADDRESS = (PROTOCOL = IPC)(KEY = ocache))
    )
    (CONNECT_DATA =
      (SID = ocache )
    )
  )
```

```
ora_ocache_origin =
  (DESCRIPTION =
    (ADDRESS_LIST =
      (ADDRESS = (PROTOCOL = TCP)(HOST = oracle8i)(PORT = 1529))
    )
    (CONNECT_DATA =
      (SERVICE_NAME = G816 )
    )
  )
```

b. Configuring the Cache Database

At the end of the installation, the Oracle Database Cache configuration assistant is invoked.

Or the configuration assistant can be invoked manually to set up later:

```
$ $ORACLE_HOME/bin/wtacca -create -option
```

where option can be typical or custom.

The following are the data required by the configuration assistant:

Screen 1. Origin Database Credentials

- * SYSDBA username and password of the origin database

Note: You need not give the connect string for the origin database in this screen, it is automatically picked up from the \$ORACLE_HOME/network/admin/tnsnames.ora file. This screen does not take up the connect string. (See known issues below)

Screen 2. Cache Information (only in case of Custom option)

- * Cache Node on which the cache database is going to reside
- * The port number through which the cache is going to be administered
- * The name of the cache. The default is 'Machine_name-cache'

Screen 3: Cache Size (only in case of Custom option)

- * Memory to be allocated for Cache (default is 25M)
- * Disk Space allocated for the Cache (default is 32M)
- * The Cache DataFile Specification. (default is \$ORACLE_HOME/dbs/users01.dbf)

Screen 4: Summary

- * This contains the summary of all of the above

Screen 5: Cache Configuration Assistant Progress

- * Preparing the Origin Database
- * Configuring the Cache
- * Configuring the Origin Database
- * Configuring the Cache Communication
- * Configuring the Management Engine Component
- * Updating User List

If the progress fails, it would report a "Processing Failed" and the error can be seen by clicking on the Show Detail button.

The installation log files can be found in \$ORACLE_HOME/install directory.

Now the Oracle Database Cache is ready for use.

3. Installing the Oracle Database Cache for OEM

The Oracle8i iCache is available with the DBA studio of OEM 2.2 or above. If you do not have an installation already, then you can install the same on MS Windows platforms using the Oracle8i Cache Manager for OEM CD shipped with the IAS 1.0.0.0.0 CD pack. This can be applied on OEM 2.1 as well.

Complete the Installation using the Oracle8i Cache Manager for OEM Installation Guide.

Recreating a Cache Database

There are times when you would like to:

- a. Recreate the existing Oracle8i cache database
- b. Recreate the Oracle8i cache database with a different origin database

Basic Operations:

1. Remove all the cached tables from the cache database using the OEM
2. Shutdown the cache database using the 'cachshut' command
3. Drop the user ORACACHE and ORACACHE\$ users from the origin database

- a. Recreate the Existing Oracle8i Cache Database

1. Start up the Oracle8i Cache Configuration Assistant

\$wtacca -create -option

where option is 'typical' or 'custom'

2. Complete the creation of the Oracle8i cache database

b. Changing the Origin Database

1. Edit the tnsnames.ora file of the Oracle8i cache.
2. Change the description for 'ora_ocache_origin' to point to the new origin database.
3. Prepare the new origin database as mentioned in <Note:117145.1> - Installing Oracle8i Cache
4. Invoke the Oracle8i Cache Configuration Assistant as mentioned above and complete the creation of the Oracle8i cache database.

Caution:

1. Dropping the Oracache user would drop all the cached tables from the cache database. Make sure that you want to delete the cache database before doing this.
2. Never delete the database, control and log files found in \$ORACLE_HOME/dbs of the ocache database. Deleting these files is NOT a step to recreate or

drop the icache database. If these files are deleted, the entire Oracle8i cache software has to be reinstalled as these are the files created by during the installation.

Create Oracle8i cache after failure during installation

Before going through creation steps, make sure that the origin database is up and running and you can ping oracle server

The following steps has to be carried out to create Oracle8i cache

1. You need to modify TNSNAME.ORA file which create during installation of Oracle8i cache under %ORACLE_HOME%\netowkr\admin as follows

```
ORA_ICACHE_ORIGIN =
(DESCRIPTION =
  (ADDRESS_LIST =
    (ADDRESS = (PROTOCOL = TCP)(HOST = <new host>)(PORT = 1521))
  )
  (CONNECT_DATA =
    (SID = <sid>)
    (SERVER = DEDICATED)
  )
)
```

2. Test the above alias using

```
tnsping ora_icache_origin
```

3. Run the following command from DOS session

```
wtacca -create -custom
```

4. Enter username and password for origin database with sysdba privileges

5. Enter administrator password to create the required services for cache

6. Proceed with creation

Note: you will get WTE-1592 error while system trying to process the phase

"Update User List" <Bug:1463140>

7. Update user list by doing the following:

1. Load DBA Studio (Standalon)
2. Add Origin database (File --> Add database to tree)
3. Use local TNSNAMES.ORA option
4. Choose origin database and connect with sys account
5. Double click the over "Caches"
6. Start cache by clicking on cache database and change "Cache State"
7. Right click on cache from tree abd select "Update User List"

Preinstallation Check List for DB Cache on Windows NT

Items to be Checked on Icache Machine

=====

1. Recommended RAM between 512 meg and 1 gig.
2. Middle tier platform only. There should not be other Oracle products running on the machine icache will be installed on.
3. Stop all background processes that are running
4. Login as Administrator and make sure the user Administrator is assigned to the ora_dba and administrator groups.
5. Make sure the Administrator has a password assigned.

6. Verify the icache machine has connectivity to the origin machine, and the origin computer has connectivity with the icache computer.

Items to be Checked on Origin Machine

=====

1. Check the Oracle temp table spaces to make sure there is at least 20 megs assigned

2. Stop and restart the database to make sure the database is fully started without errors.

3. Stop and restart the listener. Use the lsnrctl utility to check the status. There should be a service for both the origin database and the external procedure?

4. While in lsnrctl, set the display mode to verbose and verify the database is registered with the listener.

5. Next verify the tnsnames.ora is configured for external procedures. Use the alias extproc_connection_data and connect with SQL*Plus. SQL*Plus should return an ORA-3113 if external procedures are configured correctly.

6. Check the c:\Temp directory to make sure it is shared with full permissions.

7. Make sure the OS user (Administrator) is assigned to the ora_dba and administrator groups.

8. Variables TMP and TEMP should be set to c:\temp

9. Install Service Pack 6 (SP6)

9.3 Object Caching Service for Java

10.

Document: Done

10.1.2 RWServlet

10.1.3 Report Security

The purpose of this document is provide instructions for the installation of the integration of reports security into Oracle Portal 3.0. Read the whole document throughly before starting.

A Detailed overview with a step by step guide to the use of Report Security in Oracle Portal is available as a White Paper at <http://technet.oracle.com/products/reports> called Security Tips in Oracle Reports Services Release 6i with Oracle Portal Release 3.0

Installing Report Security Integration with Oracle Portal

=====

STEP 1

Although Report Security integration was supported with Oracle Portal from reports version 6.0.8.11.x, there were a number of problems with the installation scripts. You need Patch 4 with Patch 1710849 (available on metalink) or Patch 5 (when available)

STEP 2

The reports security should be run into a clean installation of Oracle Portal. That is, one which does not have a previous version of the report security from a previous release or earlier patch or base release.

STEP 3

Create the following roles manually

RW_ADMINISTRATOR

RW_DEVELOPER

RW_BASIC_USER

RW_POWER_USER

then grant RW_ADMINISTRATOR to PORTAL30;

STEP 4

To install the report security you need to run the script rwwwvins.sql

This script is available in {ORACLE_HOME}\report60\server\security and not in the directory {ORACLE_HOME}\report60\server as specified in the documentation. This has been logged as a documentation bug

You will get the error:

```
BEGIN :l_verstr := wwv_standard_util.get_version; END;
*
```

```
ERROR at line 1:
ORA-06550: line 1, column 38:
PLS-00302: component 'GET_VERSION' must be declared
ORA-06550: line 1, column 7:
PL/SQL: Statement ignored
```

This call gets the version of portal you have installed and runs the relevant scripts this is expected and as it fails it will automatically run the 3.0 scripts. If you have any other version e.g. Webdb 2.2 or 2.1 this will work and therefore runs the correct script.

STEP 5

Once the script has been run successfully in Portal under the Administer tab instead of seeing 'Report Server Administration' you may see the following:

Missing string(reports_security_desc) language(us) domain (wwc) sub_domain (sec)

The links should still valid and you can define report servers and reports successfully but all of the titles are incorrect.

Solution on NT/2000

This problem should have been fixed in patch 4 so please contact Oracle Support if you see this.

Solution on UNIX

(see bug 1650642):

- a. deinstall by running the script `rwdeinst.sql`. as follows:

```
$ sqlplus /nolog @rwdeinst.sql
```

- b. Then, run the `sqlldr` command, make sure you are in the

```
$ORACLE_HOME/reports60/admin/security/ directory and set your
```

environment to the run the database utilities. Then issue the command:

```
$ sqlldr userid=portal30/portal30@<connectstring> control=repus30.ctl
```

where <connectstring> is the value you entered for your tnsnames.ora entry in the previous two script prompts.

c. Then run the original pl/sql installation script again:

```
$ sqlplus /nolog @rwwwvins.sql
```

Explanation:

The sqlloader command in pl/sql installation scripts failed to run, and sqlloader doesn't populate all NLS strings into database table therefore it has to be run manually.

10.2 Oracle9iAS Discoverer Viewer

10.2.1 Discoverer viewer

1. Launch the 'Services' window from the Control Panel.
2. Only the following Oracle Services need to be reset for Automatic Startup:
 - ? OracleDiscoverer4i
 - ? OracleiDSDataTNSListener
 - ? OracleiSuitesAgent
 - ? OracleiSuitesDataGatherer
 - ? OracleiSuitesHTTPServer
 - ? OracleServiceORCL
3. The Service **OracleiDSDataHTTPServer** should be set stopped and set to manual startup.
4. Reboot the system.
5. We must manually register the Discoverer Services with the application server's object request broker.
6. From the 'Start' menu, run 'Programs ⌘ Oracle Discoverer Server 4i Setup ⌘ **Register Collector**'. When completed, you may close the DOS windows.
7. From the 'Start' menu, run 'Programs ⌘ Oracle Discoverer Server 4i Setup ⌘ **Register Preferences**'. When completed, you may close the DOS windows.
8. From the 'Start' menu, run 'Programs ⌘ Oracle Discoverer Server 4i Setup ⌘ **Register Session**'. When completed, you may close the DOS windows

10.2.2 Setting Up Discoverer

Installing the Tutorial Data:

Discoverer comes with a tutorial. This tutorial enables people to train informally to use its many features. Tutorials are available for both End Users and Administrators. In this section, we are going to install the tutorial data, which will serve as a basis for this review. Before beginning, you must have access to a database account with 'System' level privileges. These are required only to install the new data, and not to run queries.

The tutorial installation is described in detail in [Chapter 4](#) of the **Discoverer Administration Guide**. The basic steps are copied here for your convenience.

1. Discoverer Start the Administration Edition.

If you are using Windows 95 or Windows NT, choose **Oracle Discoverer 4 ⌘ Discoverer Administration Edition** from the Start menu.

2. This displays the Connect to Oracle Discoverer Administration Edition dialog box. Specify a Username/password with DBA privileges. For a default Oracle 8.1.6 installation, this could be **System/Manager@orcl**.

Leave the Connect field blank if you are logging into your default database (local machine).

If you are logging into an Oracle database that is not your default database, specify the appropriate Oracle Net8 connect string. See your database administrator if you do not know the connect string.

3. Click Connect.

4. If this is the first time you are logging in to Discoverer, you will receive a warning that “**You do not have access to any End User Layer [EUL]...Do you want to create an EUL Now?**”.

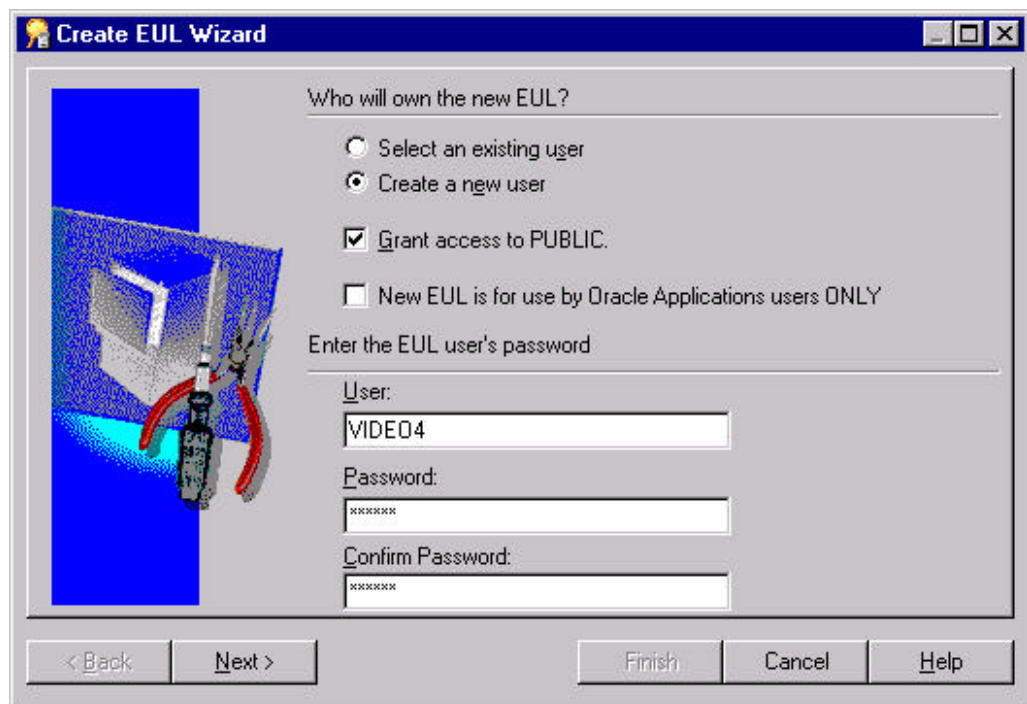

Click on [Yes] to enter the EUL Manager dialog box..

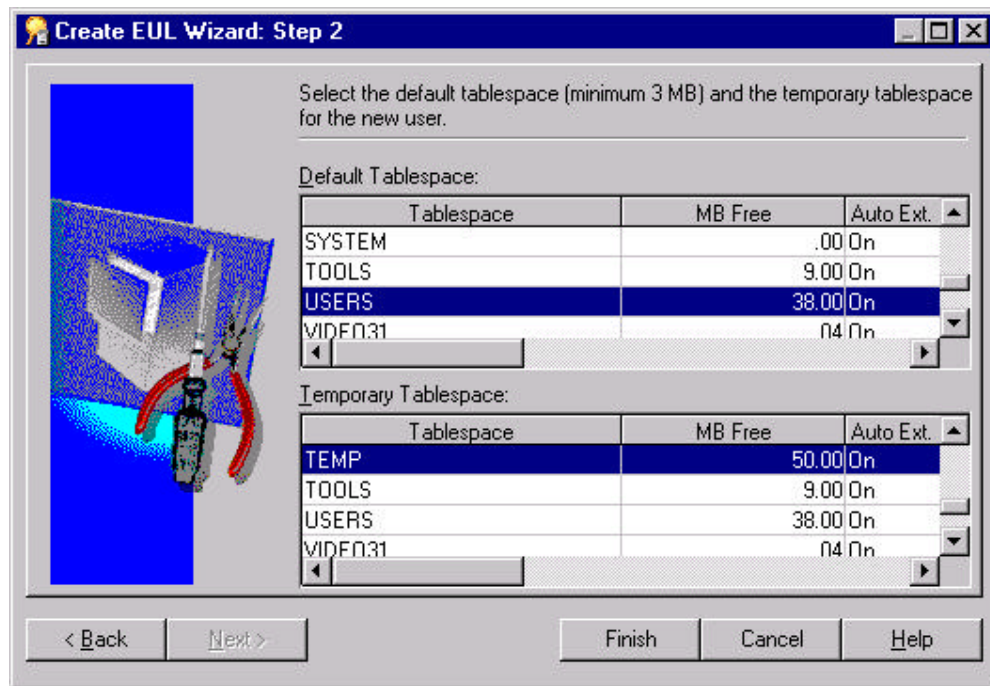

5. Within the EUL Manager, click on [Create an EUL] to begin.

6. The Create EUL Wizard opens. Use this wizard to create your user ID for this tutorial. Make the following selections and text entries:

- ? Select Create a new user.
- ? In the User field, specify VIDEO4
- ? In the Password field, repeat your user ID (VIDEO4), and confirm it.

7. Click [Next]. This displays the Create EUL Wizard: Step 2.

8. Select the default and temporary tablespaces. For example, select **USERS** as your default tablespace and **TEMP** as your temporary tablespace.

9. Click [**Finish**].

10. When complete, the Discoverer Administration Edition displays a message telling you that the EUL has been created successfully. Click **OK**.

11. You have successfully created an EUL.

The Discoverer Administration Edition asks if you want to install the tutorial in the EUL. Click [**Yes**].

This displays the Install Tutorial Wizard: Step 1. Note that your tutorial user ID is in the EUL text box.

12. Click [**Next**].

13. This displays the Install Tutorial Wizard: Step 2. Note that **VIDEO4** is specified in the User field. In the Password field, specify **VIDEO4**.

14. Click [**Finish**].

15. When Discoverer Administration Edition has completed the installation, a message tells you that the tutorial data has been installed. Click [**OK**].

16. You are then asked if you want to connect as the owner of the EUL that you have just created. Click [**Yes**].

17. The **Load Wizard** opens automatically. Select '**Open an Existing Business Area**' to see the Video Tutorial business area.

Install End User Layer Analysis Workbooks

The Discoverer End User Layer (EUL) also serves as a repository for user defined queries, usage statistics, and Discoverer privileges, providing valuable feedback on query performance, query volume, usage patterns, etc.. This information is readily accessible through ad-hoc reporting or predefined reports.

Discoverer includes a series of pre-defined worksheets to assist Administrators in analyzing query patterns and EUL content. The installation procedure for this workbook is described in **Appendix B** of the **Discoverer Administration Guide**. For simplicity, these steps are also detailed below:

1. Use SQL*Plus to run the SQL file 'EUL4.sql' as the EUL Owner,
For example:

C:\SQLPlus

or from:

Start *≡* Programs *≡* Oracle - iDSDData *≡* Application Development *≡* SQL*Plus

2. At the “Enter User Name” prompt:

<eul owner>/<eul owner password>

where <eul owner>>/<eul owner password> is **video4/video4** based upon the previous section

3. At the prompt, type the following:

```
SQL> Start D:\{ORACLE HOME}\discvr4\sql\EUL4.sql
```

Where {ORACLE HOME} is the path to where Discoverer Administration is installed, and ‘D’ is the drive letter you installed to. The {Oracle Home} should be ‘Oracle\806’ based upon the preceding installation instructions.

4. This creates some custom PL/SQL functions required by the Discoverer V4 EUL business area.

5. **Exit** the SQL session.

6. Start Discoverer Administration Edition. (Start *≡* Programs *≡* Oracle Discoverer 4 *≡* Discoverer Administration Edition)

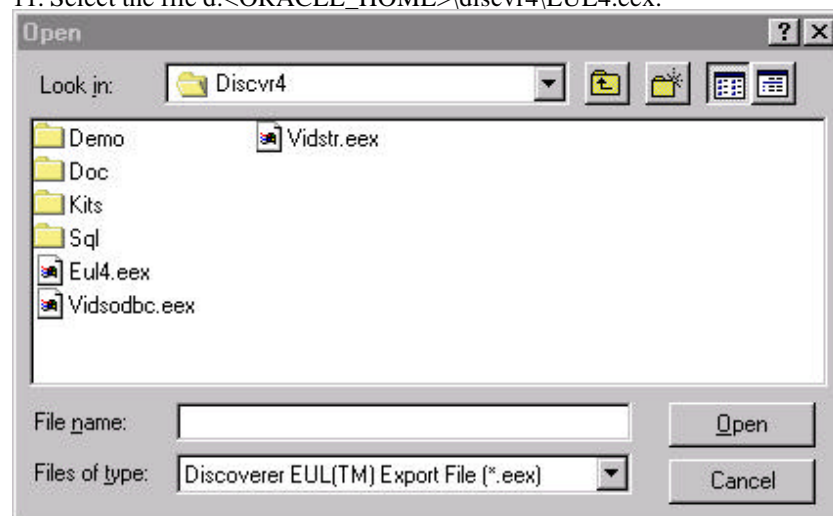

7. Connect as the EUL owner. If you followed the installation ‘tips’ above, this will be Video4/Video4.

8. At the Load Wizard, hit [Cancel].

9. From the menu bar, select **F**ile *≡* **I**mport

10. The Import Wizard is displayed. Click on the [**A**dd] button.

11. Select the file d:<ORACLE_HOME>\discvr4\EUL4.eex.

12. Click **[Open]**
13. Accept the defaults, and Click **[Next]** to continue.
14. Click **[Start]** to begin the import.
15. When you see the **'Import Successful'** message, Click **[Finish]**. This completes the import.
16. You may exit Discoverer Administration.

The Eul Data Definition and Query Statistics workbooks are now accessible from the Discoverer clients: Discoverer Desktop, Discoverer Plus, and Discoverer Viewer. We will run these later in our review.

Summary Management - Setup

Discoverer Administrators require additional database privileges if they are to use the Automated Summary Management features. Procedures to grant these privileges are described in **Chapter 2.2** of the **Discoverer Administration Guide - "Summary Management"**.

If you are connecting to an existing data source, you should review this chapter in its entirety to ensure that you are set up correctly. If you installed the database according to the directions above, the relevant steps are replicated below for your convenience. Please contact your system administrator if you have any questions regarding this, or need additional assistance.

Privileges

1. From the 'Start' menu, choose Start \approx Run. Type in SVRMGR. A DOS Window will appear.
2. At the prompt, type **CONNECT INTERNAL**
3. Issue the following command to grant select access on required system objects:
SQL> grant select on v_\$parameter to public;
4. If you are connecting to an existing database and wish to enable query prediction, verify that the following privileges have been granted:
SQLDBA> grant select on v_\$session to public;
SQLDBA> grant select on v_\$sesstat to public;
5. Type **'Exit'** to end your session.
6. Log onto SQL*Plus as the Administrator. From the start menu, select Start \approx Programs \approx Oracle - iDSData \approx Application Development \approx SQL Plus
7. In the Log On window, enter **'System'** for the user name and **'Manager'** as the password. Click on **[OK]** to connect.
8. Execute the following SQL statement:
SQL> @D:\Oracle\806\discvr4\sql\eulasm.sql
where 'D:' is the drive letter where you installed Oracle iDS.
9. At the prompt to **"Enter Value for User Name:"** type **'Video4'**, where VIDEO4 is the user we created when we installed the Tutorial Data.

Confirming that DBMS_JOBS is Installed

The Oracle Batch Manager is utilized to enable the scheduling of updates to summary tables and materialized views. The following steps determine if this is set up correctly. *You will only need to perform this check these quotas if you are connecting to an existing database. The default installation above supports this facility.*

1. Within the SQL Plus window you previously opened, Execute the following SQL statement:

```
SQL> select * from all_objects where object_name='DBMS_JOB' and object_type = 'PACKAGE';
```

If the statement returns no rows, use your DBA SQLDBA (Oracle 7.2) or SVRMGRL (Oracle 7.3 or later) to create the necessary packages. Please refer to chapter 5 of the Discoverer Administration Guide for further details.

Determining Tablespace Quotas

A user must have enough quota in their default tablespace to create summary tables. You will only need to check these quotas if you are connecting to an existing database.

1. Return to your SQL Plus session.

2. At the prompt

```
SQL> select * from dba_ts_quotas where username = <user>;
```

where <user> is the userid of the person using the Administration Edition, i.e. VIDEO4. Unlimited tablespace is represented by a '-1'.

3. Reset the Tablespace Quotas by issuing the following SQL statement:

```
SQL> alter user <user> quota <n> on <tablespace>;
```

where <user> is the userid of the person using the Administration Edition where <n> is the quota in K(ilobytes) or M(egabytes) or Unlimited where <tablespace> is the default tablespace name e.g. USERS

Checking Object/Schema Name

A user should not have an object in their schema with the same name as their username. *This step is only necessary if you are connecting to an existing database.*

1. To check that this is not the case, login to SQL*Plus as the user and issue the following command:

```
SQL> select object_name from user_objects where object_name = <user>;
```

Database Initialization Parameters

To enable summary management, we need to make the following modifications. This step applies to both existing databases as well as a locally installed database.

1. Locate INIT<SID>.ORA. The file INITORCL.ORA is located in <ORACLE_HOME>\database. The <SID> in this case is ORCL. If you installed the database on the server following these instructions, you can locate it in D:\ORACLE\iDSData\database\initORCL.ora where 'D:' is the drive letter where you installed the database.

2. Edit the file to include the following lines:

```
?   timed_statistics = TRUE
```

- ? job_queue_processes = 2
- ? job_queue_interval = 600 (Note: this is equivalent to 10 minutes)

3. Close the file and save your changes.
4. Shut down and restart the server to effect this change.

12.2.3 Discoverer Viewer on DHCP

The Oracle9iAS installation process assumes that the target server has a fixed IP address. However, most Oracle field employees are running under DHCP.

The following configuration changes have enabled Discoverer Viewer to work in this environment. Please note that this method is not officially supported, and may affect other 9iAS applications.

disco4iviewer.properties

The disco4iviewer.properties file defines the servlet used by the Discoverer Viewer. This file is located in { *OracleiASHome* }\Apache\Jserv\servlets. If you followed the instructions above, you will find this file in:

D:\ORACLE\iSuites\Apache\Jserv\servlets

where 'D:' is the drive letter you installed to.

1. Make a copy of file disco4iviewer.properties.
2. Open file disco4iviewer.properties.
3. Scroll to the bottom of the file, until you see the section “# Lines for disco4iviewer.properties”
4. For each line that begins “**servlet.Viewer.initArgs**”, there is a url of the format “http://*machinename*:*port*#/disco4iv/...”
5. Modify the *machinename* to be *machinename.domain*. For example:

Before:

```
servlet.Viewer.initArgs=config=http://mlstern-lap:80/disco4iv/html/disco4iv.xml
```

After:

```
servlet.Viewer.initArgs=config=http://mlstern-lap.us.oracle.com:80/disco4iv/html/disco4iv.xml
```

Where 'mlstern-lap' is the machine name and 'us.oracle.com' is the domain name.

6. Save your changes and exit.

httpd.conf

The httpd.conf file defines listener environment used by 9iAS and the Discoverer Viewer servlet. This file is located in { *OracleiASHome* }\Apache\Apache\conf. If you followed the instructions above, you will find this file in:

D:\ORACLE\iSuites\Apache\Apache\conf

where 'D:' is the drive letter you installed to.

1. Make a copy of file httpd.conf.
2. Open file httpd.conf.
3. Search for the string "**ServerName**".
4. Modify the ServerName from *MachineName* to *MachineName.Domain*. For example:
ServerName MLSTERN-LAP to
ServerName MLSTERN-LAP.us.oracle.com
5. Save your changes and exit.
6. Stop the service OracleiSuitesHTTPServer.
7. Restart the service OracleiSuitesHTTPServer.

10.2.4 Discoverer Viewer Test

Discoverer Viewer should be executable via url:

<http://MachineName.Domain/discoverer4i/viewer>

where the *MachineName.Domain* is the ServerName provided in step 4 above.

11.

11.1 Oracle Enterprise Manager

11.2 Oracle Internet Directory

12. Oracle Servlet Engine mod_ose

- ORACLE 8.1.7 & 9IAS 1.0.2.X

12.1 Introduction

12.1.1 Overview

Oracle 8.1.7 (Oracle 8I R3) Oracle Servlet Engine(OSE)
Oracle HTTP Server mod_ose module Apache OSE
module . Apache OSE Protocol Net8 HTTP
Tunneling . request connection Mod_jserv
mod_ose stateful application client OSE connection

Oracle Servlet Engine

1. Servlet 2.2 spec, JSP 1.1 spec
2. OSE' JNDI namespace servlet publish
3. Stateful, Stateless servlet
4. Stateful servlet database session
5. Apache web server mod_ose access가

12.1.2 OSE

- 1 Oracle 8I, Net8
- 2 Session shell DB
- 3 Web Service
- 4 Web Domain
- 5 Web Service Endpoint
 - 5.1 Oracle Net8 Listener (HTTP Service dynamically register to listener)
 - 5.2 Oracle Net8 Listener (HTTP Service statically configured it listener.ora)
 - 5.3 Oracle Dispatcher directly
 - 5.4 Oracle HTTP Server (Apache) and mod_ose
- 6 Servlet Contexts
- 7 Servlet Publication
- 8

12.2 Oracle 8i, Net8

12.2.1 Oracle 8i

Oracle Jserver, MTS

Init.ora

```
shared_pool_size = 50M      ( MTS          )
java_pool_size = 20M       ( EJB          )
compatible = 8.1.0

mts_dispatchers = "(PROTOCOL=TCP)"
mts_dispatchers = "(PROTOCOL=TCP)(PRE=oracle.aurora.server.SGiopServer)"

# OSE Endpoint statically configured in listener.ora
# TCP dispatcher (generic) for OSE access over listener
mts_dispatchers = "(ADDRESS=(PROTOCOL=TCP))(DISPATCHERS=1)"
# TCP dispatcher (for myWebServer service only) for OSE access over listener
mts_dispatchers = "(ADDRESS=(PROTOCOL=TCP))(DISP=1)(PRE=http://myWebService)"

# OSE endpoint using dispatcher only
# mts_dispatchers = "(ADDRESS=(PROTOCOL=TCP)(PORT=8080))(DISP=1)(PRE=http://admin)"
mts_dispatchers =
"(ADDRESS=(PROTOCOL=TCP)(PORT=8080))(DISP=1)(PRE=http://myWebService)"

# OSE endpoint for apache mod_ose
mts_dispatchers = "(ADDRESS=(PROTOCOL=TCP))(DISPATCHERS=1)(SERVICE=MODOSE)"

mts_dispatchers = "(PROTOCOL=TCP)(PRE=oracle.aurora.server.SGiopServer)"
# Uncomment the following line when your listener is configured for SSL
# (listener.ora and sqlnet.ora)
# mts_dispatchers = "(PROTOCOL=TCPS)(PRE=oracle.aurora.server.SGiopServer)"
```

12.2.2 Net8

Listener.ora

```
LISTENER =
  (DESCRIPTION_LIST =
    (DESCRIPTION = (ADDRESS = (PROTOCOL = IPC)(KEY = EXTPROC1)) )
    (DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = jweom)(PORT = 1521)) )
    (DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = jweom)(PORT = 1521))
      (PROTOCOL_STACK = (PRESENTATION = http://myWebService) ) )
    (DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = jweom)(PORT = 2481))
      (PROTOCOL_STACK = (PRESENTATION = GIOP) (SESSION = RAW) ) )
  )

    )
  )

INST2_HTTP.KR.ORACLE.COM =
  (DESCRIPTION =
    (ADDRESS_LIST =
      (ADDRESS = (PROTOCOL = TCP)(HOST = jweom)(PORT = 1521))
    )
    (CONNECT_DATA =
      (SERVER = SHARED) (SERVICE_NAME = MODOSE)
      (PRESENTATION = http://myWebService)
    )
  )
```

12.2.3 Java

DB User

```
DB User java class Oracle Jserver
SQL> grant javasyspriv ( javauserpriv ) to scott;
, Oracle Servlet Engine Document Root File System
dbms_java.grant_permission
SQL> exec dbms_java.grant_permission('SCOTT',
'SYS:java.io.FilePermission','f:\9ias\demo\test.txt','read');
```

12.2.4 Javac

, servlet , sqlj, ejb

class

```
<ORACLE_HOME>\lib\aurora_client.jar;
<ORACLE_HOME>\lib\aurora_server.jar;
<ORACLE_HOME>\lib\vbjapp.jar;
<ORACLE_HOME>\lib\vbjorb.jar;
<ORACLE_HOME>\lib\sqlj\lib\runtime.zip;
<ORACLE_HOME>\jdbc\lib\translator.zip;
<ORACLE_HOME>\jdbc\lib\classes12.zip;
<ORACLE_HOME>\jdbc\lib\jndi.zip;
<ORACLE_HOME>\lib\servlet.jar;
```

12.2.5 Note

```
Oracle Jserver <ORACLE_HOME>/javavm/readme.txt
Oracle Jserver <ORACLE_HOME>/javavm/jahome/Settings.properties
```

12.3 Session Shell

12.3.1 Session Shell

Sess_sh (session shell) database instance session namespace
Oracle 8i tool .

Syntax

```
sess_sh -user user -password password -service serviceURL
```

-user specifies the user name of the schema.

-password specifies the password for the specified user name.

-service specifies the URL of the database whose session namespace is to be "opened" by sess_sh. The serviceURL parameter should have one of the three following forms:

```
sess_iiop://host:port:sid
```

```
jdbc:oracle:type:spec
```

```
http://host[:port]
```

Following are some general examples:

```
sess_iiop://localhost:2481:orcl
```

```
jdbc:oracle:thin:@myhost:1521:orcl
```

```
http://localhost:8000
```

)

```
C:\>sess_sh -u sys/manager -s sess_iiop://jweom:2481:MINIMAX
```

```
--Session Shell--
```

```
--type "help" at the command line for help message
```

```
$ exit
```

```
C:\>sess_sh -u sys/manager -s jdbc:oracle:thin:@jweom:1521:MINIMAX
```

```
--Session Shell--
```

```
--type "help" at the command line for help message
```

```
$
```

12.3.2 Web Service

```

destroywebdomain <domain_name>
webdomain      servlet context
)
destroywebdomain /webservice

```

12.3.4 Web Service Endpoint

Web Service network entity endpoint, web service endpoint
 endpoint HTTP Listener HTTP Dispatcher

HTTP Endpoint Oracle8i OSE option

- Oracle Net Listener
 - HTTP Service dynamically register to listener
 - HTTP Service statically configured it listener.ora
- Oracle Dispatcher directly
- Oracle HTTP Server (Apache) and mod_ose

```

Syntax
addendpoint [options] <service> <name>
[-listener <lsnr>]
[-net8]
[-interface <int_spec>]
[-port <port_num>]
[-register]
[-ssl]
[-threads <min> <max>]
[-timeout <seconds>]

)
addendpoint -port 8080 -threads 3 5 -timeout 300 webservice endpt1

```

⚡ HTTP Service dynamically register to listener

```

$ addendpoint -port 1521 myWebService endpt_static

INIT.ORA
# 1. TCP dispatcher (generic) for OSE access over Listener
# mts_dispatchers = "(ADDRESS=(PROTOCOL=TCP))(DISPATCHERS=1)"
# 2. TCP dispatcher (for myWebServer service only) OSE access over Listener
# mts_dispatchers =
"(ADDRESS=(PROTOCOL=TCP))(DISP=1)(PRE=http://myWebService)"
LISTENER :
# Listener static configuration for myWebServer running in OSE
# (ADDRESS = (PROTOCOL = TCP)(HOST = ukp15002)(PORT =1521))
# (PROTOCOL_STACK = (PRESENTATION = http://myWebService))
#
TNSNAMES : No setup

```

⚡ HTTP Service statically configured in listener.ora

```
$ addendpoin -port 1522 -register myWebService endpt_dynamic
```

```
INIT.ORA
```

```
# 1. TCP dispatcher (generic) for OSE access over Listener
mts_dispatchers = "(ADDRESS=(PROTOCOL=TCP))(DISPATCHERS=1)"
# 2. TCP dispatcher (for myWebServer service only) OSE access over Listener
mts_dispatchers =
"(ADDRESS=(PROTOCOL=TCP))(DISP=1)(PRE=http://myWebService)"
LISTENER : No setup
TNSNAMES : No setup
```

⚡ Oracle Dispatcher directly

```
$ addendpoin -port 8080 myWebService endpt_disp
```

```
INIT.ORA
```

```
# HTTP dispatcher for direct access to OSE (for myWebServer service only)
mts_dispatchers = "(ADDRESS=(PROTOCOL=TCP)(PORT=8080))(DISP=1)
(PRE=http://myWebService)"
LISTENER : No setup
TNSNAMES : No setup
```

⚡ Oracle HTTP Server (Apache) and mod_ose

```
$ addendpoin -net8 myWebService endpt_ose
```

```
INIT.ORA
```

```
# TCP dispatcher for access over Apache mod_ose
mts_dispatchers =
"(ADDRESS=(PROTOCOL=TCP))(DISP=1)(SERVICE=MODOSE)"
```

```
LISTENER : Generic TCP listener on any port (example 1521)
```

```
TNSNAMES :
```

```
INST2_HTTP =
```

```
(DESCRIPTION =
  (ADDRESS_LIST =
    (ADDRESS = (PROTOCOL = TCP)(HOST = jweom)(PORT = 1521))
  )
  (CONNECT_DATA =
    (SERVER = SHARED)
    (SERVICE_NAME = MODOSE)
    (PRESENTATION = http://myWebService)
  )
)
```

<ORACLE_HOME>/Apache/Apache/conf/mod__ose.conf

```
LoadModule ose_module      modules/orajipa8i.dll
<IfModule mod_ose.c>
AuroraService inst2_http
#
# Context for VPATH /myWebApp/
#
<Location /myWebApp/ >
AddHandler aurora-server snoop
</Location>
<Location /myWebApp/* >
SetHandler aurora-server
</Location>
<Location /myWebApp/myHelloServlet >
SetHandler aurora-server
</Location>
</IfModule
```

```
rmendpoint <service> <name>
    service endpoint listener endpoint
)
$ rmendpoint webservice endpt1
```

12.3.5 Servlet Contexts

URL URI Virtual path servlet, configuration parameter,
JSP, file system static

```
Syntax
createcontext [options] <domain_name> <context_name>
-virtualpath <path>
[-recreate]
[-properties <prop_groups>]
[-docroot <location>]
[-stateless]
)
createcontext -virtualpath /SCOTT -docroot /private/scott/html /ScottRoot ScottContext
```

```
$ createcontext -virtualpath /myWebApp -docroot f:\9ias\demo /myWebServer myWebApp
```

```
destroycontext <context_name>
webdomain servlet, servlet context, servlet configuration
```

12.3.7 Servlet Publication

Oracle8i	loadjava	create java	load	Servlet classes	session shell
publishServlet		Servlet context	publish	.	publishing
Servlet	Servlet context	subdirectory	JNDI object	.	

Servlet

```
) Hello.java
=====
import javax.servlet.*;
import javax.servlet.http.*;

public class Hello extends HttpServlet {
    int i =0 ;
    public void doPost ( HttpServletRequest req, HttpServletResponse res )throws
ServletException, java.io.IOException {
        res.setContentType("text/html");
        java.io.PrintWriter out = new java.io.PrintWriter(res.getOutputStream());
        i++;
        out.println("<HTML> <BODY>");
        out.println("This is the Servlet from Database Hit is "+ i);
        out.println("</BODY></HTML>");
        out.flush();
        out.close();
    }
    public void doGet( HttpServletRequest req, HttpServletResponse res )throws
ServletException, java.io.IOException {
        doPost( req,res);
    }
}
```

Servlet Compile

```
F:\9ias\demo>javac Hello.java
```

Servlet Load

```
F:\9ias\demo>loadjava -r -f -v -u scott/tiger@minimax Hello.class
initialization complete
loading : Hello
creating : Hello
resolver :
resolving: Hello
```

Servlet publication

Syntax

```
publishservlet [options] <context_name> <servlet_name> <class_name>
[-virtualpath <path>]
[-stateless]
[-reuse]
[-properties props]
)
    publishservlet -virtualpath /hello /websdomains/contexts/default helloServlet
SCOTT>HelloWorld
```

```
)
$ publishservlet -virtualpath /myHelloServlet /myWebServer/contexts/myWebApp
myHelloServlet SCOTT>Hello
```

```
unpublishservlet <context_name> <servlet_name>
```

```
$ chown -R SCOTT /myWebServer
$ chmod -R +rwx SCOTT /myWebServer
```

13.Oracle 9I AS Container for J2EE

- Oracle9iAS and J2EE Overview
- OC4J Server
- Overview of Configuration files
- Basic ConfigurationTasks
 - Setting Up an Oracle DataSource
 - Naming / JNDI
 - Setting Up OC4J with Apache
 - Running simple Servlet, JSP and EJB
 - Setting Up Security
 - Setting Up RMI over HTTP
 - Setting up JMS Queue
- Packaging and Deploying J2EE Applications
 - Using JARs, WARs and EAR files
- Basics of HTTP Clustering and Load-Balancing

13.1 Oracle9iAS and J2EE Overview

Oracle 9iAS Release 1.0.2.2

JDK VM

J2EE Container

- Complete J2EE 1.2 and partial J2EE 1.3 implementation
- Lightweight
- Small memory footprint
- High Performance
- XML file based configuration for all aspects of server, web server and applications
- Simplified installation, configuration, deployment and administration
- Auto deployment and “Hot” deployment of J2EE Applications
- Clustering, Load balancing and Fail-over of Web Applications

13.2 OC4J Server

13.2.1 Requirements

OC4J	JDK 1.2.2_07	1.3.xxx
configuration file	install directory, lib/ subdirectory,	EAR, WAR, ejb-jar files
		CLASSPATH 가

13.2.2

```
% cd $ORACLE_HOME
% unzip oc4j.zip
% cd j2ee/home (<oc4j-home> )
% java -jar orion.jar -install
```

Directory Structure
<oc4j-home>

- *application-deployments/*
- *applications/*
- *config/*
- *database/*
- *lib/*
- *log/*
- *default-web-app/*

13.2.3

13.2.3.1 Default Startup

```
% java -jar orion.jar
```

“Oracle9iAS (1.0.2.2) Containers for J2EE initialized”

-console Administration Console (OC4J가
 Error가 가 admin.jar console
)
 -quiet Standard output message
 -version Version
 -help Help

13.2.5 OC4J Server

13.2.5.1

% java -jar admin.jar ormi://<host>:<port> <admin id> <admin password> -
 shutdown

13.2.5.2

% java -jar admin.jar ormi://<host>:<port> <admin id> <admin password> -
 shutdown force

option

<host> hostname

<port> <oc4j-home>/config/rmi.xml rmi-server port default port
 23791

<admin_password> OC4J install admin password <oc4j-
 home>config/principals.xml

13.2.6 OC4J Server

13.2.6.1

% java -jar admin.jar ormi://<host><port> <admin id> <admin password> <options>

option list:

ormi://<host>:<port> : Port 23791 rmi.xml

-shutdown

OC4J Server

-restart

OC4J Server

OC4J server가

-deploy -file <EAR> -targetPath <remote_node_path>

Deploys (redeploys) an application. Supply application information in the following sub-switches:

-file: enterprise archive to deploy

-deploymentName: application deployment name

-targetPath: path on the remote node to deploy archive into. Default is applications directory.

-bindWebApp <app_deploy_name> <web_app_name> <web_site_name> <context_root>

Binds a Web application to the specified site and root.

-installDataSource

Installs a new DataSource. Supply information within the following sub-switches

-jar: path to the JAR file containing the driver that is to be added to the server's library.

-url: The JDBC database URL

-location: The namespace location for the raw source. For example, jdbc/DefaultPooledDS.

-pooledLocation: The namespace location for the pooled source. For example, jdbc/DefaultPooledDS.

-xaLocation: The namespace location for the XA source. For example, jdbc/xa/DefaultXADS.

-cmtLocation: The namespace location for the CMT source.

For example, jdbc/DefaultDS. This is the source usually used by applications.

-application <name>

-connectionDriver: The JDBC database driver class. For example, 'com.mydb.Driver'.

13.2.7 Console GUI

```
%java -jar orionconsole.jar
```

13.3 Overview of OC4J Configuration Files

Chart Title

13.3.1 OC4J Configuration Files Relationship

13.3.2 Overview of the Server.xml

13.3.2.1 Server.xml

Server configuration information

global application
global web application

default web site served.
 The library-path
 Maximum number of HTTP connections
 Logging settings
 Java compiler settings
 Cluster ID
 Transaction timeout
 SMTP host
 Pointers to data-sources, rmi, jms XML files
 And your applications entries

Example of Server.xml

```

<application-server>
  application-auto-deploy-directory="<auto-deploy-ears>
  application-directory=" ../applications"
  deployment-directory=" ../application-deployments"

  <rmi-config path=" ../rmi.xml" />
  <jms-config path=" ../jms.xml" />
  <log> <file path=" ../log/server.log" /> </log>

  <global-application name="default" path="application.xml" />

  <global-web-app-config path="global-web-application.xml" />
  <web-site path=" ../default-web-site.xml" />

  <application auto-start="true" deployment-directory="<dir>" parent="<parentApps>"
  <application name="news" path=" ../applications/news.ear" />
  <application name="petstore" path=" ../applications/petstore.ear" />
</application-server>
  
```

13.3.3 Overview of [Default-]Web-Site.xml

Default-web-site.xml, Web-site.xml contain configuration for each web-site served including:

Hostname/IP, virtual hosts settings for this site, port to listen
 Default web application for the site
 .war file name and *root context* for web applications
 The access-log format
 Settings for user web applications
 SSL configuration

Example Web-Site.xml

```

<web-site host="<hostname>" port="<n>" cluster-island="1" display-name="<WebSite>"
secure="false" use-keep-alives="true"
  virtual-hosts="<hostname>, ..., <hostname>" />

<default-web-app application="defaultAppEAR" name="defaultAppWAR" shared="false"
load-on-startup="false" />
  
```

```

<web-app application="<app>" name="<web-app>" root="/root_context" shared="false"
load-on-startup="false" />

<user-web-apps max-inactivity-time="n" path="<path>" />

<access-log format="<format spec>" path="<path>" suffix="<suffix>"
split="none|hour|day|week|month" />
/>

```

13.3.4 OC4J-Specific Deployment files

- Contain deployment information for different components
- Used by the deployer to map *environment entries*, *resources references*, and *security-roles* to actual deployment-specific values
- You can create and edit them manually but they are automatically generated when using auto-deployment.

Example of Using OC4J-Specific Deployment file

Declaration of enterprise bean's reference to an external resource (datasource, JMS queue, mail session, etc)

```

<resource-ref>
  <description>no description</description>
  <res-ref-name>jdbc/EstoreDataSource</res-ref-name>
  <res-type>javax.sql.DataSource</res-type>
  <res-auth>Container</res-auth>
</resource-ref>

```

The resource-ref-mapping maps a reference to an external resource such as a datasource, JMS queue, mail session (ties the resource to a JNDI-location)

<resource-ref-mapping

location="jdbc/nonPooledDS" name="jdbc/EstoreDataSource" / >

13.4 Oracle Data Source

13.4.1 Data-source tags

name: The displayed name of the DataSource

class-entry: The classname of the DataSource

connection-driver: "oracle.jdbc.driver.OracleDriver"

location: JNDI path to non-pooled connections

pooled-location: JNDI path to pooled connections

xa-location: JNDI path to pooled + distributed transaction aware connections

ejb-location: JNDI name for pooled + distributed transactional +

EJB-aware connections for Servlet, JSP and EJBs

url: the JDBC connection string for the database

username/password: in order to avoid hardcoding in application code

13.4.2 Example of data-sources.xml

```
<data-sources>
  <data-source
    class="com.evermind.sql.DriverManagerDataSource"
    name="Oracle"
    schema="database-schemas/oracle.xml"
    location="jdbc/nonPooledDS"
    xa-location="jdbc/xa/OracleXADS"
    ejb-location="jdbc/PooledDS"
    pooled-location="jdbc/pooled/DefaultPooledDS"
    connection-driver="oracle.jdbc.driver.OracleDriver"
    username="scott"
    password="tiger"
    url="jdbc:oracle:thin:@<hostname>:1521:<ORCL SID>"
    inactivity-timeout="30"
  />
</data-sources>
)
<?xml version="1.0"?>
<!DOCTYPE data-sources PUBLIC "Orion data-sources"
"http://xmlns.oracle.com/ias/dtds/data-sources.dtd">
<data-sources>
```

```

        <data-source
            class="com.evermind.sql.DriverManagerDataSource"
            name="OracleDS"
            location="jdbc/OracleCoreDS"
            xa-location="jdbc/xa/OracleXADS"
            ejb-location="jdbc/OracleDS"
            connection-driver="oracle.jdbc.driver.OracleDriver"
            username="scott"
            password="tiger"
            url="jdbc:oracle:thin:@jweom:1521:ORA817"
            inactivity-timeout="30"
        />
    </data-sources>

```

13.4.3 Servlet Connecting to Oracle DataSource

```

import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;
import java.util.*;
import javax.naming.*;
import java.sql.*;
import javax.sql.*;

public class DataSourceServlet extends HttpServlet {
    InitialContext context = null;
    DataSource jdbcURL = null;
    Connection conn = null;

13.6 Security in OC4J

13.6.1 Define Users and Groups in Principals.xml

```
<group name="allusers">
  <description>Group for all normal users</description>
  <permission name="rmi:login" />
  <permission name="com.evermind.server.rmi.RMIPermission" />
</group>
...
<users>
  <user deactivated="false" locked="true|false"
    username="guest" password="welcome">
    realname="<real name>" username="<userName>"
    <certificate-issuer> CN="<X509-CA>" </certificate-issuer>
    <certificate-serial-id> <n> </certificate-serial-id>
    <group-membership group="allusers" />
  </user>
  ...
</users>
```

13.6.2 Set Up Logical Roles in *web.xml* or *ejb-jar.xml* or *application.xml*

```
<security-role>
  <description> ...</description>
  <role-name>VISITOR</role-name>
</security-role>
```

13.6.3 Authorization in *ejb-jar.xml*

```
<method-permission>
    <role-name>VISITOR</role-name>
    <method>
        <ejb-name>customerbean</ejb-name>
        <method-name>*</method-name>
    </method>
</method-permission>
```

Mapping Logical role to group(s) in orion-web.xml or orion-ejb-jar.xml or orion-application.xml

```
<security-role-mapping name="VISITOR">
    <group-name="allusers" />
</security-role-mapping>
```

13.6.4 Setting up SSL Certificates

Copy the <oc4j-home>/config/default-web-site.xml into

```
<oc4j-home>/config/secure-web-site.xml
```

Add secure="true" as an attribute to the tag.

Add the keystore tag

Install the site in server.xml

```
<web-site path="./secure-web-site.xml" />
```

13.7 Overview of rmi.xml

13.7.1 Contains configuration for Remote Method Invocation

- The hostname/IP and port the RMI server binds to
- Remote servers to communicate to
- Clustering settings
- Log settings

```
<rmi-server>
  <server host=<remote-server> username=<adminUser> password=<passwd> />
  <cluster host="230.0.0.1" id="<n>" password="<passwd>"
    port="9127" username="<cluster-user>" />
  <log> <file path="..log/rmi.log" /> </log>
</rmi-server>
```

13.7.2 Setting Up RMI over HTTP

Tunneling firewalls with RMI

- Embed "send" data in HTTP Post
- Embed "response" in HTTP Response
- Deal with Firewalls and HTTP Ports

How To

1 - Add the following to config/global-web-applications.xml

```
<servlet>
  <servlet-name>rmi</servlet-name>
  <servlet-class>
    com.evermind.server.rmi.RMIHttpTunnelServlet
  </servlet-class>
</servlet>
```

2 - Prepend the RMI URL with "http:"

ormi://localhost/app becomes http:ormi://localhost/app

13.8 Overview of JMS.xml

Contains configuration for Java Messaging Service

- Hostname/IP and port that the JMS server binds to
- Queues and Topics to be bound in the JNDI tree.
- Log settings

```
<jms-server host="<host>.<domain>|<n.n.n.n>|ALL" port="9127" />
  <queue name="Demo Queue" location="jms/demoQueue">
    <description>A dummy queue</description>
  </queue>
  <topic name="Demo Topic" location="jms/demoTopic">
    <description>A dummy topic</description>
  </topic>
  <log> <file path=" ../log/jms.log" /> </log>
</jms-server>
```

13.8.1 Setting Up JMS Queue

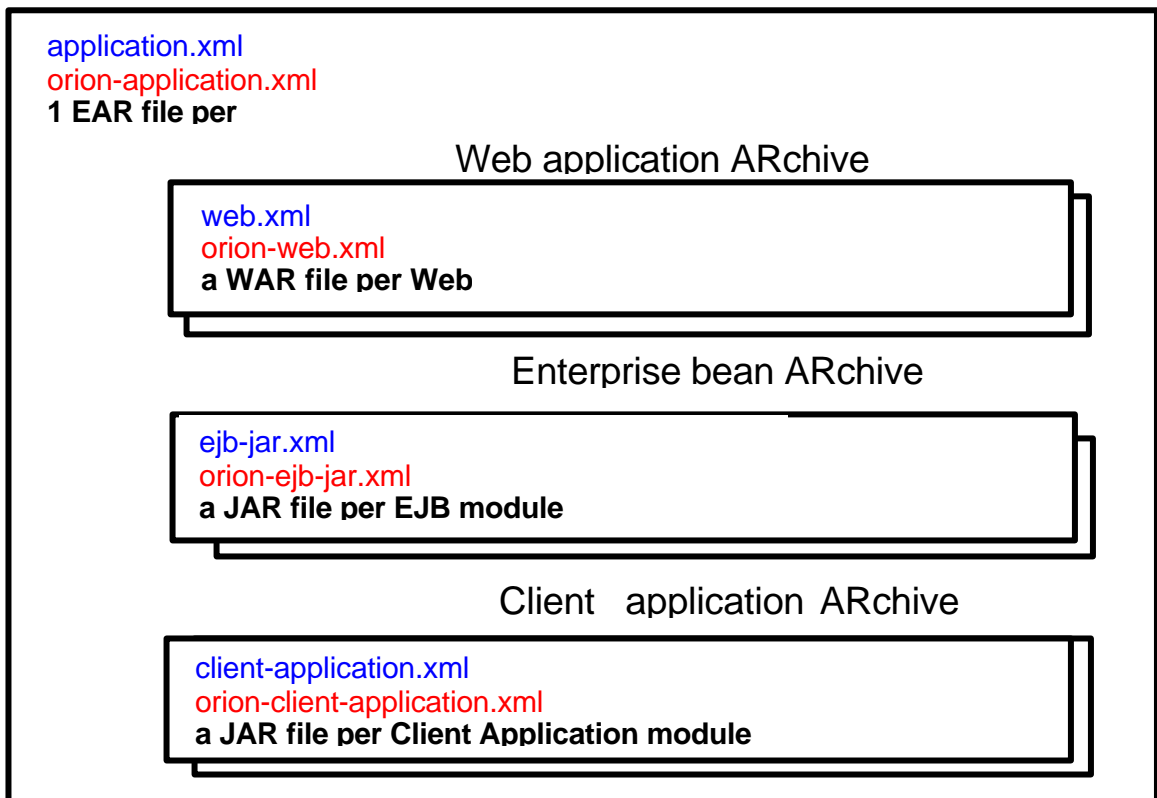

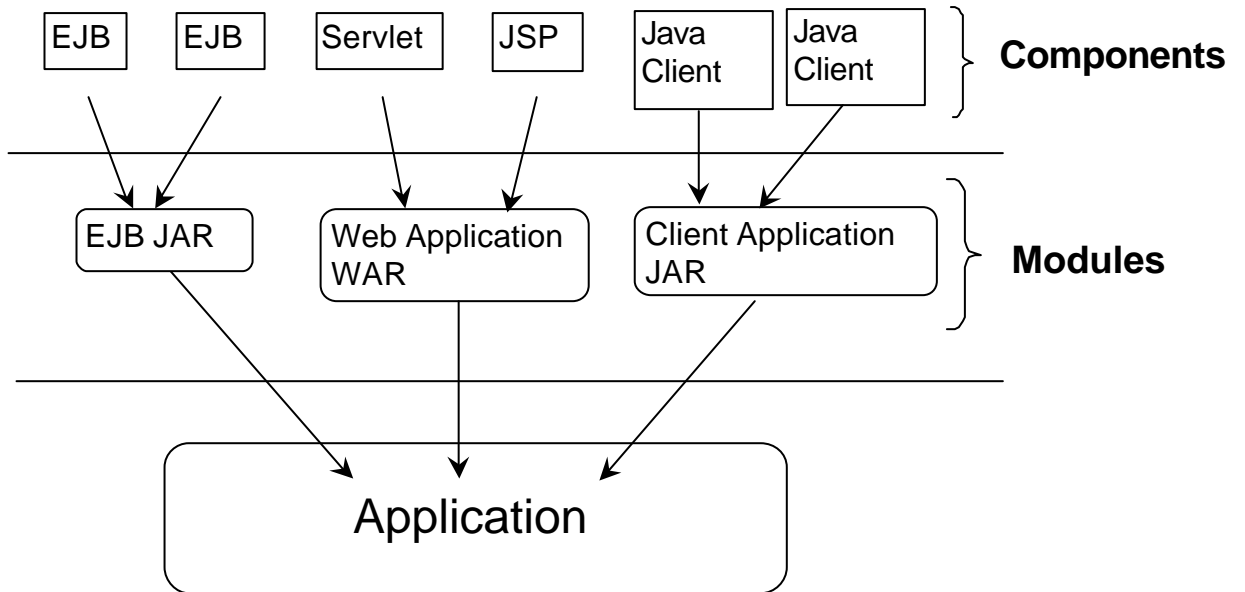

1. Enables JMS in `<oc4j-home>/config/server.xml`
2. Define/Configure JMS queue in `<oc4j-home>/config/jms.xml`
3. Looking up JMS queue from JNDI

```
QueueConnectionFactory factory =
  (QueueConnectionFactory) new InitialContext().lookup (
    "java:comp/env/jms/demoQueueConnectionFactory");

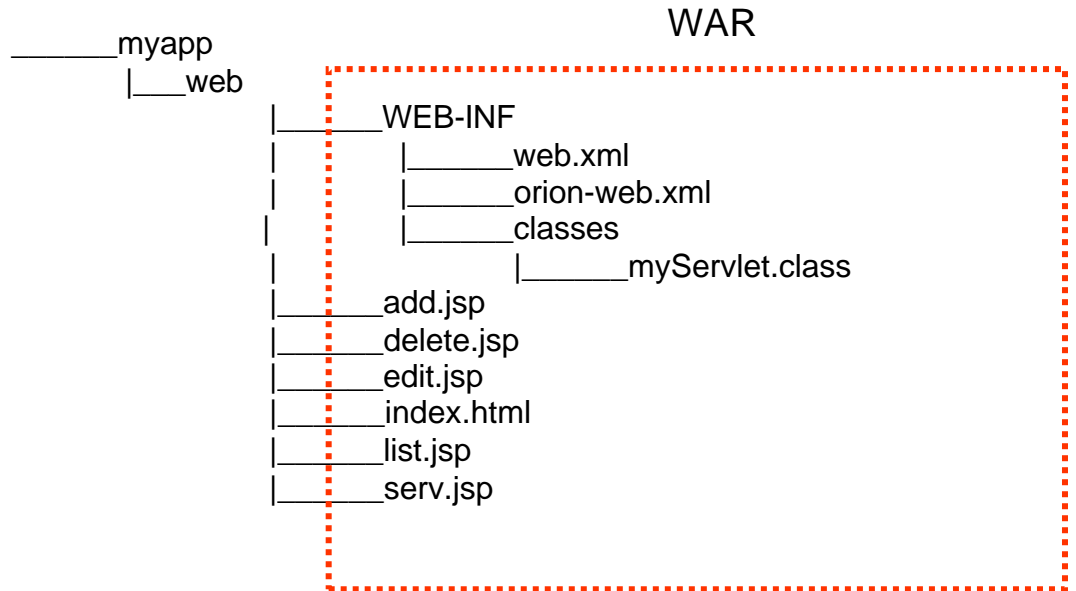

QueueConnection connection = factory.createQueueConnection();
Queue queue = (Queue) new InitialContext().lookup (
  java:comp/env/jms/demoQueue");
```

4. JMS samples in `<oc4j-home>/demo/jms/`

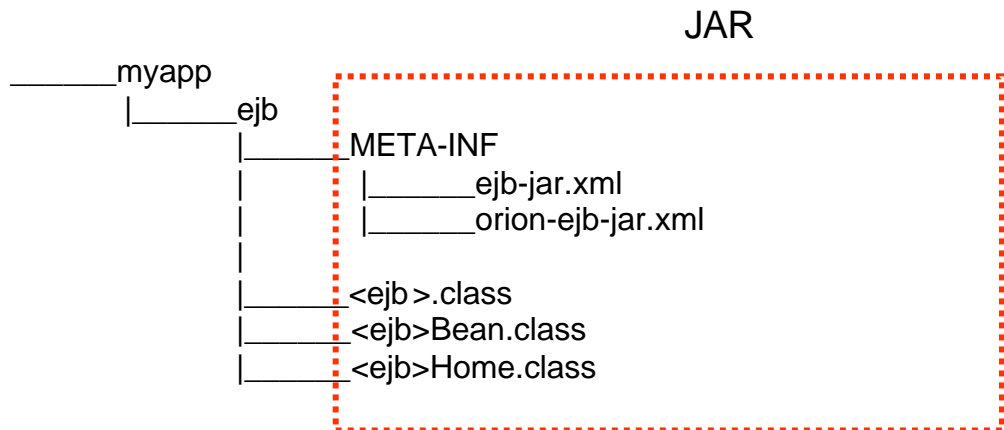

13.9 Packaging and Deploying J2EE Applications

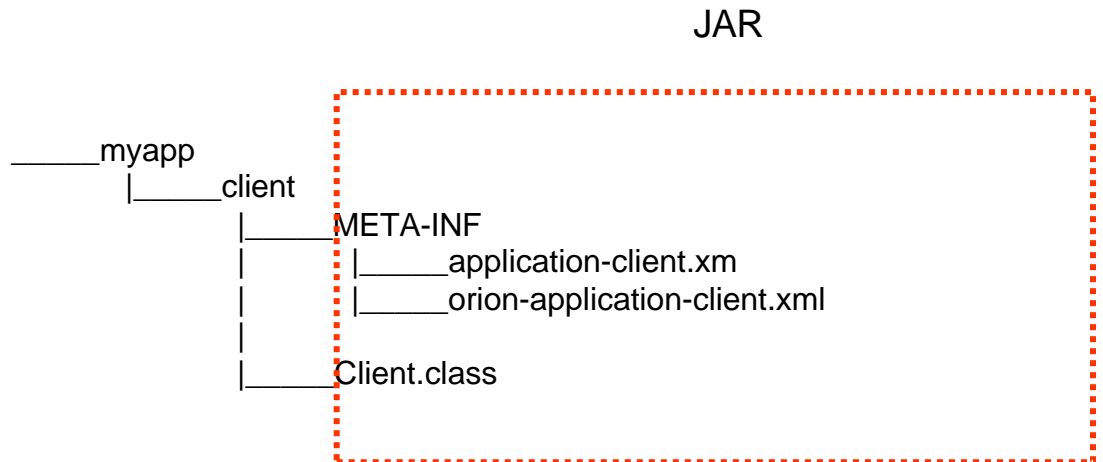

13.9.1 Web Module Structure

13.9.2 EJB Module Structure

13.9.3 Client-Application Module Structure

13.9.4 Deploying J2EE Application with OC4J

1-Package myapp as an EAR file (myapp.ear) and place it in

<oc4j-home>/applications/

2-Add the following line to <oc4j-home>/config/server.xml

<application name="myapp" path="./applications/myapp.ear" />

3-Add the following line to

- <oc4j-home>/config/default-web-site.xml or

- <oc4j-home>/config/<other>-web-site.xml

<web-app application="myapp" name "myapp-web" root="<path>" />

Application.xml

<display-name>admin</display-name>

<principals path="/principals.xml" />

<module> <ejb>petstoreEjb.jar</ejb> </module>

<module>

```

    <web>
      <web-uri>petstore.war</web-uri>
      <context-root>admin</context-root>
    </web>
  </module>
</security-role>
  <role-name>administrator</role-name>
</security-role>

```

Orion-application.xml

Contains OC4J specific application settings

- Auto-creation and deletion of Database tables for CMP EJB
- Default data source for CMP EJB
- JNDI Namespace-access
- User-manager, security-role mappings

Must be placed in META-INF/ of EAR

Auto generated to applications directory in

```
<oc4j-home>/application-deployments
```

13.9.5 Hot Deployment with OC4J

13.10 Basics of HTTP Clustering and Load-Balancing

An island replicates session state between two or more OC4J servers

A Cluster is a conglomeration of islands

13.10.1 Clustering for Fault Tolerance and Load-Balancing

Clustering requires a load-balancer, which replicates each node state to the cluster. The state is stored in-memory, not persistent

Fault-tolerance In OC4J works for both stateful and stateless requests

Stateless: OC4J redirects the client to another working instance

Stateful: The state must be available to be failed over machine; the state is propagated to the cluster at all times. This enables another node in the same island to pick up the conversation with the client.

13.10.2 Setting Up for HTTP Application Clustering and Load-Balancing

1. Cluster node OC4J Web Application Install .

2. Session Web Application Deployment Descriptor .

Node Web Application deployment descriptor file orion-web.xml
<cluster-config/> 가 . Web Application <oc4j-home>/config/global-web-application.xml <cluster-config/> tag 가 .

<oc4j-home>/application-deployments/<application-name>/<web-app-name>/orion-web.xml

<oc4j-home>/config/global-web-application.xml

```
<orion-web-app>
....
<cluster-config/>
....
</orion-web-app>
```

Load-balancer 230.0.0.1 Multicast IP address 가 가
default port 9127 port cluster id default IP address .

data HttpSession data ServletContext data .

3. cluster island

```
Load Balancing Cluster Group member Cluster Island
<oc4j-home>/config/*web-site.xml
<web-site ...cluster-island=<island id#> >
cluster Island Cluster
Island ID
```

4. OC4J Web site configuration (*web-site.xml) load-balancer Host Port

```
<oc4j-home>/config/*web-site.xml
<web-site .. >
  <frontend host=<balancer-host> port=<balancer-port />
</web-site>
```

5. Application <app>/WEB-INF/web.xml tag

```
<distributable/>
```

6. Load-balancer.xml

```
<load-balancer host=<host/ip> port=<80|439|<port> use-ip=<true> />
<island id="x">
<backend-server host="a.b.c" port="80|443" />
<ssl-config factory="my.own.SSLServerSocketFactory" keystore="mykeystore" keystore-
password="123456" needs-client-auth="true|false"
provider="com.sun.net.ssl.internal.ssl.Provider">
<property name="paramName" value="paramValue" />
```

13.10.3 Load Balancer Web application

13.10.3.1 load-balancer

```
Startup Option load-balancer.xml file
java -jar loadbalancer.jar <options>
```

13.10.3.2 OC4J Server

Load Balancer OC4J Server
Start

Option

java -Dhttp.cluster.debug=true -Dcluster.debug=true -jar orion.jar

14. Trouble Shooting Guide

14.1 Oracle HTTP Server

9iAS Configuration / Logfile

iAS Configuration Logfile snapshot shell script

: metalink.oracle.com (Notes 133985.1)

/tmp directory file

iaslogs.tar.Z - iAS log files
iasconfig.tar.Z - iAS configuration files

Warning: If you have a lot of logs, or large logs, then iaslogs.tar.Z may be quite large, so ensure sufficient space is available in /tmp.

iAS administrators. Use when requested by Oracle support. Unix platforms only.

Gather snapshot of iAS configuration & logfiles

chmod 700 iasnapshot.sh

----- CUT BELOW HERE -----

```
#!/usr/bin/sh
```

```
# Take a snapshot of the state of an iAS install  
# Andy Salt  
# Version 1.0.1 - added prompts, changed to sh.
```

```
# NOTE: Needs 'tests' added to limit size of logs (tail), but currently rough  
#        and ready
```

```
# Disclaimer: Oracle and I accept no liability for the use of this script  
#            You are responsible for the effects of running this script.
```

```

Check the link is pointing to the correct version of your JDK under

`$ORACLE_HOME/Apache.`

For example, the example below shows the 'jdk' link is pointing to JDK 1.2.2, which is correct for iAS 1.0.2.1 on the platform in this example.

```
$ ls -la $ORACLE_HOME/Apache/jdk

lrwxrwxrwx  1 iasuk  users          12 May  9 08:44
/u03/iasuk/IAS1021ENT/Apache/jdk -> /opt/java1.2
```

However, had this been JDK 1.1.8 for example, I might expect to see the error above.

Note: Not all versions of iAS include a symbolic link to the JDK. Certain platforms provide the actual JDK.

14.3.6 9iAS 1.0.2.2 Portal Oracle 9I

Portal Configuration Assistant ORA-28009

Oracle 9I init.parameter spfile parameter

O7_DICTIONARY_ACCESSIBILITY = TRUE
